## **FIELD OF THE INVENTION**

The present invention relates to novel polypeptides, and the nucleic acids encoding them,  
having properties related to stimulation of biochemical or physiological responses in a cell, a  
tissue, an organ or an organism. More particularly, the novel polypeptides are gene products of  
novel genes, or are specified biologically active fragments or derivatives thereof. Methods of use  
40 encompass diagnostic and prognostic assay procedures as well as methods of treating diverse  
pathological conditions.

## BACKGROUND OF THE INVENTION

Eukaryotic cells are characterized by biochemical and physiological processes which under normal conditions are exquisitely balanced to achieve the preservation and propagation of the cells. When such cells are components of multicellular organisms such as vertebrates, or  
5 more particularly organisms such as mammals, the regulation of the biochemical and physiological processes involves intricate signaling pathways. Frequently, such signaling pathways involve extracellular signaling proteins, cellular receptors that bind the signaling proteins, and signal transducing components located within the cells.

Signaling proteins may be classified as endocrine effectors, paracrine effectors or  
10 autocrine effectors. Endocrine effectors are signaling molecules secreted by a given organ into the circulatory system, which are then transported to a distant target organ or tissue. The target cells include the receptors for the endocrine effector, and when the endocrine effector binds, a signaling cascade is induced. Paracrine effectors involve secreting cells and receptor cells in close proximity to each other, for example two different classes of cells in the same tissue or  
15 organ. One class of cells secretes the paracrine effector, which then reaches the second class of cells, for example by diffusion through the extracellular fluid. The second class of cells contains the receptors for the paracrine effector; binding of the effector results in induction of the signaling cascade that elicits the corresponding biochemical or physiological effect. Autocrine effectors are highly analogous to paracrine effectors, except that the same cell type that secretes the autocrine  
20 effector also contains the receptor. Thus the autocrine effector binds to receptors on the same cell, or on identical neighboring cells. The binding process then elicits the characteristic biochemical or physiological effect.

Signaling processes may elicit a variety of effects on cells and tissues including by way of nonlimiting example induction of cell or tissue proliferation, suppression of growth or proliferation,  
25 induction of differentiation or maturation of a cell or tissue, and suppression of differentiation or maturation of a cell or tissue.

Many pathological conditions involve dysregulation of expression of important effector proteins. In certain classes of pathologies the dysregulation is manifested as diminished or suppressed level of synthesis and secretion of protein effectors. In other classes of pathologies  
30 the dysregulation is manifested as increased or up-regulated level of synthesis and secretion of protein effectors. In a clinical setting a subject may be suspected of suffering from a condition brought on by altered or mis-regulated levels of a protein effector of interest. Therefore there is a need to assay for the level of the protein effector of interest in a biological sample from such a subject, and to compare the level with that characteristic of a nonpathological condition. There  
35 also is a need to provide the protein effector as a product of manufacture. Administration of the effector to a subject in need thereof is useful in treatment of the pathological condition. Accordingly, there is a need for a method of treatment of a pathological condition brought on by a diminished or suppressed levels of the protein effector of interest. In addition, there is a need for a

method of treatment of a pathological condition brought on by a increased or up-regulated levels of the protein effector of interest.

Antibodies are multichain proteins that bind specifically to a given antigen, and bind poorly, or not at all, to substances deemed not to be cognate antigens. Antibodies are comprised of two short chains termed light chains and two long chains termed heavy chains. These chains are constituted of immunoglobulin domains, of which generally there are two classes: one variable domain per chain, one constant domain in light chains, and three or more constant domains in heavy chains. The antigen-specific portion of the immunoglobulin molecules resides in the variable domains; the variable domains of one light chain and one heavy chain associate with each other to generate the antigen-binding moiety. Antibodies that bind immunospecifically to a cognate or target antigen bind with high affinities. Accordingly, they are useful in assaying specifically for the presence of the antigen in a sample. In addition, they have the potential of inactivating the activity of the antigen.

Therefore there is a need to assay for the level of a protein effector of interest in a biological sample from such a subject, and to compare this level with that characteristic of a nonpathological condition. In particular, there is a need for such an assay based on the use of an antibody that binds immunospecifically to the antigen. There further is a need to inhibit the activity of the protein effector in cases where a pathological condition arises from elevated or excessive levels of the effector based on the use of an antibody that binds immunospecifically to the effector. Thus, there is a need for the antibody as a product of manufacture. There further is a need for a method of treatment of a pathological condition brought on by an elevated or excessive level of the protein effector of interest based on administering the antibody to the subject.

## SUMMARY OF THE INVENTION

The invention is based in part upon the discovery of isolated polypeptides including amino acid sequences selected from mature forms of the amino acid sequences selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94. The novel nucleic acids and polypeptides are referred to herein as NOV1a, NOV1b, NOV1c, NOV2a, NOV2b, NOV2c, NOV2d, NOV3a, NOV3b, etc. These nucleic acids and polypeptides, as well as derivatives, homologs, analogs and fragments thereof, will hereinafter be collectively designated as "NOVX" nucleic acid or polypeptide sequences.

The invention also is based in part upon variants of a mature form of the amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, wherein any amino acid in the mature form is changed to a different amino acid, provided that no more than 15% of the amino acid residues in the sequence of the mature form are so changed. In another embodiment, the invention includes the amino acid sequences selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94. In another embodiment, the invention also comprises variants of the amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94

wherein any amino acid specified in the chosen sequence is changed to a different amino acid, provided that no more than 15% of the amino acid residues in the sequence are so changed. The invention also involves fragments of any of the mature forms of the amino acid sequences selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, or any other amino acid sequence selected from this group. The invention also comprises fragments from these groups in which up to 15% of the residues are changed.

In another embodiment, the invention encompasses polypeptides that are naturally occurring allelic variants of the sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94. These allelic variants include amino acid sequences that are the translations of nucleic acid sequences differing by a single nucleotide from nucleic acid sequences selected from the group consisting of SEQ ID NOS: 2n-1, wherein n is an integer between 1 and 71. The variant polypeptide where any amino acid changed in the chosen sequence is changed to provide a conservative substitution.

In another embodiment, the invention comprises a pharmaceutical composition involving a polypeptide with an amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94 and a pharmaceutically acceptable carrier. In another embodiment, the invention involves a kit, including, in one or more containers, this pharmaceutical composition.

In another embodiment, the invention includes the use of a therapeutic in the manufacture of a medicament for treating a syndrome associated with a human disease, the disease being selected from a pathology associated with a polypeptide with an amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94 wherein said therapeutic is the polypeptide selected from this group.

In another embodiment, the invention comprises a method for determining the presence or amount of a polypeptide with an amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94 in a sample, the method involving providing the sample; introducing the sample to an antibody that binds immunospecifically to the polypeptide; and determining the presence or amount of antibody bound to the polypeptide, thereby determining the presence or amount of polypeptide in the sample.

In another embodiment, the invention includes a method for determining the presence of or predisposition to a disease associated with altered levels of a polypeptide with an amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94 in a first mammalian subject, the method involving measuring the level of expression of the polypeptide in a sample from the first mammalian subject; and comparing the amount of the polypeptide in this sample to the amount of the polypeptide present in a control sample from a second mammalian subject known not to have, or not to be predisposed to, the disease, wherein an alteration in the expression level of the polypeptide in the first subject as compared to the control sample indicates the presence of or predisposition to the disease.

In another embodiment, the invention involves a method of identifying an agent that binds to a polypeptide with an amino acid sequence selected from the group consisting of SEQ ID

NO:2n, wherein n is an integer between 1 and 71 or is 94, the method including introducing the polypeptide to the agent; and determining whether the agent binds to the polypeptide. The agent could be a cellular receptor or a downstream effector.

5 In another embodiment, the invention involves a method for identifying a potential therapeutic agent for use in treatment of a pathology, wherein the pathology is related to aberrant expression or aberrant physiological interactions of a polypeptide with an amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, the method including providing a cell expressing the polypeptide of the invention and having a property or function ascribable to the polypeptide; contacting the cell with a composition  
10 comprising a candidate substance; and determining whether the substance alters the property or function ascribable to the polypeptide; whereby, if an alteration observed in the presence of the substance is not observed when the cell is contacted with a composition devoid of the substance, the substance is identified as a potential therapeutic agent.

15 In another embodiment, the invention involves a method for screening for a modulator of activity or of latency or predisposition to a pathology associated with a polypeptide having an amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, the method including administering a test compound to a test animal at increased risk for a pathology associated with the polypeptide of the invention, wherein the test animal recombinantly expresses the polypeptide of the invention; measuring the activity of the  
20 polypeptide in the test animal after administering the test compound; and comparing the activity of the protein in the test animal with the activity of the polypeptide in a control animal not administered the polypeptide, wherein a change in the activity of the polypeptide in the test animal relative to the control animal indicates the test compound is a modulator of latency of, or predisposition to, a pathology associated with the polypeptide of the invention. The recombinant  
25 test animal could express a test protein transgene or express the transgene under the control of a promoter at an increased level relative to a wild-type test animal. The promoter may or may not be the native gene promoter of the transgene.

30 In another embodiment, the invention involves a method for modulating the activity of a polypeptide with an amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, the method including introducing a cell sample expressing the polypeptide with a compound that binds to the polypeptide in an amount sufficient to modulate the activity of the polypeptide.

35 In another embodiment, the invention involves a method of treating or preventing a pathology associated with a polypeptide with an amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, the method including administering the polypeptide to a subject in which such treatment or prevention is desired in an amount sufficient to treat or prevent the pathology in the subject. The subject could be human.

40 In another embodiment, the invention involves a method of treating a pathological state in a mammal, the method including administering to the mammal a polypeptide in an amount that is

sufficient to alleviate the pathological state, wherein the polypeptide is a polypeptide having an amino acid sequence at least 95% identical to a polypeptide having the amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94 or a biologically active fragment thereof.

5 In another embodiment, the invention involves an isolated nucleic acid molecule comprising a nucleic acid sequence encoding a polypeptide having an amino acid sequence selected from the group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94; a variant of a mature form of the amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer  
10 between 1 and 71 or is 94 wherein any amino acid in the mature form of the chosen sequence is changed to a different amino acid, provided that no more than 15% of the amino acid residues in the sequence of the mature form are so changed; the amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94; a variant of the amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an  
15 integer between 1 and 71 or is 94, in which any amino acid specified in the chosen sequence is changed to a different amino acid, provided that no more than 15% of the amino acid residues in the sequence are so changed; a nucleic acid fragment encoding at least a portion of a polypeptide comprising the amino acid sequence selected from the group consisting of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94 or any variant of the polypeptide wherein any  
20 amino acid of the chosen sequence is changed to a different amino acid, provided that no more than 10% of the amino acid residues in the sequence are so changed; and the complement of any of the nucleic acid molecules.

In another embodiment, the invention comprises an isolated nucleic acid molecule having a nucleic acid sequence encoding a polypeptide comprising an amino acid sequence selected  
25 from the group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, wherein the nucleic acid molecule comprises the nucleotide sequence of a naturally occurring allelic nucleic acid variant.

In another embodiment, the invention involves an isolated nucleic acid molecule including a nucleic acid sequence encoding a polypeptide having an amino acid sequence selected from the  
30 group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94 that encodes a variant polypeptide, wherein the variant polypeptide has the polypeptide sequence of a naturally occurring polypeptide variant.

In another embodiment, the invention comprises an isolated nucleic acid molecule having a nucleic acid sequence encoding a polypeptide comprising an amino acid sequence selected  
35 from the group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, wherein the nucleic acid molecule differs by a single nucleotide from a nucleic acid sequence selected from the group consisting of SEQ ID NOS: 2n-1, wherein n is an integer between 1 and 71 or is 94.

In another embodiment, the invention includes an isolated nucleic acid molecule having a  
40 nucleic acid sequence encoding a polypeptide including an amino acid sequence selected from the

group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, wherein the nucleic acid molecule comprises a nucleotide sequence selected from the group consisting of the nucleotide sequence selected from the group consisting of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71; a nucleotide sequence wherein one or more nucleotides in the nucleotide sequence selected from the group consisting of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71 is changed from that selected from the group consisting of the chosen sequence to a different nucleotide provided that no more than 15% of the nucleotides are so changed; a nucleic acid fragment of the sequence selected from the group consisting of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71; and a nucleic acid fragment wherein one or more nucleotides in the nucleotide sequence selected from the group consisting of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71 is changed from that selected from the group consisting of the chosen sequence to a different nucleotide provided that no more than 15% of the nucleotides are so changed.

In another embodiment, the invention includes an isolated nucleic acid molecule having a nucleic acid sequence encoding a polypeptide including an amino acid sequence selected from the group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, wherein the nucleic acid molecule hybridizes under stringent conditions to the nucleotide sequence selected from the group consisting of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, or a complement of the nucleotide sequence.

In another embodiment, the invention includes an isolated nucleic acid molecule having a nucleic acid sequence encoding a polypeptide including an amino acid sequence selected from the group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, wherein the nucleic acid molecule has a nucleotide sequence in which any nucleotide specified in the coding sequence of the chosen nucleotide sequence is changed from that selected from the group consisting of the chosen sequence to a different nucleotide provided that no more than 15% of the nucleotides in the chosen coding sequence are so changed, an isolated second polynucleotide that is a complement of the first polynucleotide, or a fragment of any of them.

In another embodiment, the invention includes a vector involving the nucleic acid molecule having a nucleic acid sequence encoding a polypeptide including an amino acid sequence selected from the group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94. This vector can have a promoter operably linked to the nucleic acid molecule. This vector can be located within a cell.

In another embodiment, the invention involves a method for determining the presence or amount of a nucleic acid molecule having a nucleic acid sequence encoding a polypeptide including an amino acid sequence selected from the group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94 in a sample, the method including providing the sample; introducing the sample to a probe that binds to the nucleic acid molecule; and determining the presence or amount of the probe bound to the nucleic acid molecule, thereby determining the presence or amount of the nucleic acid molecule in

the sample. The presence or amount of the nucleic acid molecule is used as a marker for cell or tissue type. The cell type can be cancerous.

In another embodiment, the invention involves a method for determining the presence of or predisposition for a disease associated with altered levels of a nucleic acid molecule having a nucleic acid sequence encoding a polypeptide including an amino acid sequence selected from the group consisting of a mature form of the amino acid sequence given SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94 in a first mammalian subject, the method including measuring the amount of the nucleic acid in a sample from the first mammalian subject; and comparing the amount of the nucleic acid in the sample of step (a) to the amount of the nucleic acid present in a control sample from a second mammalian subject known not to have or not be predisposed to, the disease; wherein an alteration in the level of the nucleic acid in the first subject as compared to the control sample indicates the presence of or predisposition to the disease.

The invention further provides an antibody that binds immunospecifically to a NOVX polypeptide. The NOVX antibody may be monoclonal, humanized, or a fully human antibody. Preferably, the antibody has a dissociation constant for the binding of the NOVX polypeptide to the antibody less than  $1 \times 10^{-9}$  M. More preferably, the NOVX antibody neutralizes the activity of the NOVX polypeptide.

In a further aspect, the invention provides for the use of a therapeutic in the manufacture of a medicament for treating a syndrome associated with a human disease, associated with a NOVX polypeptide. Preferably the therapeutic is a NOVX antibody.

In yet a further aspect, the invention provides a method of treating or preventing a NOVX-associated disorder, a method of treating a pathological state in a mammal, and a method of treating or preventing a pathology associated with a polypeptide by administering a NOVX antibody to a subject in an amount sufficient to treat or prevent the disorder.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, suitable methods and materials are described below. All publications, patent applications, patents, and other references mentioned herein are incorporated by reference in their entirety. In the case of conflict, the present specification, including definitions, will control. In addition, the materials, methods, and examples are illustrative only and are not intended to be limiting.

Other features and advantages of the invention will be apparent from the following detailed description and claims.

## **DETAILED DESCRIPTION OF THE INVENTION**

The present invention provides novel nucleotides and polypeptides encoded thereby. Included in the invention are the novel nucleic acid sequences, their encoded polypeptides, antibodies, and other related compounds. The sequences are collectively referred to herein as

"NOVX nucleic acids" or "NOVX polynucleotides" and the corresponding encoded polypeptides are referred to as "NOVX polypeptides" or "NOVX proteins." Unless indicated otherwise, "NOVX" is meant to refer to any of the novel sequences disclosed herein. Table A provides a summary of the NOVX nucleic acids and their encoded polypeptides.

Table A indicates the homology of NOVX polypeptides to known protein families. Thus, the nucleic acids and polypeptides, antibodies and related compounds according to the invention corresponding to a NOVX as identified in column 1 of Table A are useful in therapeutic and

diagnostic applications implicated in, for example, pathologies and disorders associated with the known protein families identified in column 5 of Table A.

Pathologies, diseases, disorders and condition and the like that are associated with NOVX sequences include, but are not limited to: e.g., cardiomyopathy, atherosclerosis, hypertension, congenital heart defects, aortic stenosis, atrial septal defect (ASD), vascular calcification, fibrosis, atrioventricular (A-V) canal defect, ductus arteriosus, pulmonary stenosis, subaortic stenosis, ventricular septal defect (VSD), valve diseases, tuberous sclerosis, scleroderma, obesity, metabolic disturbances associated with obesity, transplantation, osteoarthritis, rheumatoid arthritis, osteochondrodysplasia, adrenoleukodystrophy, congenital adrenal hyperplasia, prostate cancer, diabetes, metabolic disorders, neoplasm; adenocarcinoma, lymphoma, uterus cancer, fertility, glomerulonephritis, hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, immunodeficiencies, psoriasis, skin disorders, graft versus host disease, AIDS, bronchial asthma, lupus, Crohn's disease; inflammatory bowel disease, ulcerative colitis, multiple sclerosis, treatment of Albright Hereditary Osteodystrophy, infectious disease, anorexia, cancer-associated cachexia, cancer, neurodegenerative disorders, Alzheimer's Disease, Parkinson's Disorder, immune disorders, hematopoietic disorders, and the various dyslipidemias, schizophrenia, depression, asthma, emphysema, allergies, the metabolic syndrome X and wasting disorders associated with chronic diseases and various cancers, as well as conditions such as transplantation, neuroprotection, fertility, or regeneration (*in vitro* and *in vivo*).

NOVX polypeptides of the present invention show homology to, and contain domains that are characteristic of members of such protein families. Details of the sequence relatedness and domain analysis for each NOVX are presented in Example A.

The NOVX nucleic acids and polypeptides are used to screen for molecules, which inhibit or enhance NOVX activity or function. Specifically, the nucleic acids and polypeptides according to the invention are used as targets for the identification of small molecules that modulate or inhibit associated diseases.

The NOVX nucleic acids and polypeptides are also useful for detecting and differentiating specific cell types, tissues, pathological tissues, cell activation states and the like. Details of expression analysis for each NOVX are presented in Example C. Accordingly, the NOVX nucleic acids, polypeptides, antibodies and related compounds according to the invention have diagnostic and therapeutic applications in the detection of a variety of diseases with differential expression in normal vs. diseased tissues, e.g. detection of cancer.

Additional utilities for NOVX nucleic acids and polypeptides according to the invention are disclosed herein.

#### **NOVX clones**

The NOVX nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications and as a research tool. These include serving as a specific or selective nucleic acid or protein diagnostic and/or prognostic marker, wherein the presence or amount of the nucleic acid or the protein are to be assessed, as well as potential therapeutic

applications such as the following: (i) a protein therapeutic, (ii) a small molecule drug target, (iii) an antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), (iv) a nucleic acid useful in gene therapy (gene delivery/gene ablation), and (v) a composition promoting tissue regeneration *in vitro* and *in vivo* (vi) a biological defense weapon.

5           In one specific embodiment, the invention includes an isolated polypeptide comprising an amino acid sequence selected from the group consisting of: (a) a mature form of the amino acid sequence selected from the group consisting of SEQ ID NO: 2n, wherein n is an integer between 1 and 71 or is 94; (b) a variant of a mature form of the amino acid sequence selected from the group consisting of SEQ ID NO: 2n, wherein n is an integer between 1 and 71 or is 94, wherein any  
10 amino acid in the mature form is changed to a different amino acid, provided that no more than 15%, no more than 10%, no more than 5% no more than 2% or no more than 1% of the amino acid residues in the sequence of the mature form are so changed; (c) an amino acid sequence selected from the group consisting of SEQ ID NO: 2n, wherein n is an integer between 1 and 71 or is 94; (d) a variant of the amino acid sequence selected from the group consisting of SEQ ID  
15 NO:2n, wherein n is an integer between 1 and 71 or is 94 wherein any amino acid specified in the chosen sequence is changed to a different amino acid, provided that no more than 15%, no more than 10%, no more than 5% no more than 2% or no more than 1% of the amino acid residues in the sequence are so changed; and (e) a fragment of any of (a) through (d).

          In another specific embodiment, the invention includes an isolated nucleic acid molecule  
20 comprising a nucleic acid sequence encoding a NOVX polypeptide comprising an amino acid sequence selected from the group consisting of: (a) a mature form of the amino acid sequence given SEQ ID NO: 2n, wherein n is an integer between 1 and 71 or is 94; (b) a variant of a mature form of the amino acid sequence selected from the group consisting of SEQ ID NO: 2n, wherein n is an integer between 1 and 71 or is 94 wherein any amino acid in the mature form of the chosen  
25 sequence is changed to a different amino acid, provided that no more than 15%, no more than 10%, no more than 5%, no more than 2%, or no more than 1% of the amino acid residues in the sequence of the mature form are so changed; (c) the amino acid sequence selected from the group consisting of SEQ ID NO: 2n, wherein n is an integer between 1 and 71 or is 94; (d) a variant of the amino acid sequence selected from the group consisting of SEQ ID NO: 2n, wherein  
30 n is an integer between 1 and 71 or is 94, in which any amino acid specified in the chosen sequence is changed to a different amino acid, provided that no more than 15%, no more than 10%, no more than 5%, no more than 2%, or no more than 1% of the amino acid residues in the sequence are so changed; (e) a nucleic acid fragment encoding at least a portion of a polypeptide comprising the amino acid sequence selected from the group consisting of SEQ ID NO: 2n,  
35 wherein n is an integer between 1 and 71 or is 94 or any variant of said polypeptide wherein any amino acid of the chosen sequence is changed to a different amino acid, provided that no more than 15%, no more than 10%, no more than 5%, no more than 2%, or no more than 1% of the amino acid residues in the sequence are so changed; and (f) the complement of any of said nucleic acid molecules.

In yet another specific embodiment, the invention includes an isolated nucleic acid molecule, wherein said nucleic acid molecule comprises a nucleotide sequence selected from the group consisting of: (a) the nucleotide sequence selected from the group consisting of SEQ ID NO: 2n-1, wherein n is an integer between 1 and 71; (b) a nucleotide sequence wherein one or more nucleotides in the nucleotide sequence selected from the group consisting of SEQ ID NO: 2n-1, wherein n is an integer between 1 and 71 is changed from that selected from the group consisting of the chosen sequence to a different nucleotide provided that no more than 15%, no more than 10%, no more than 5%, no more than 2%, or no more than 1% of the nucleotides are so changed; (c) a nucleic acid fragment of the sequence selected from the group consisting of SEQ ID NO: 2n-1, wherein n is an integer between 1 and 71; and (d) a nucleic acid fragment wherein one or more nucleotides in the nucleotide sequence selected from the group consisting of SEQ ID NO: 2n-1, wherein n is an integer between 1 and 71 is changed from that selected from the group consisting of the chosen sequence to a different nucleotide provided that no more than 15%, no more than 10%, no more than 5%, no more than 2%, or no more than 1% of the nucleotides are so changed.

#### **NOVX Nucleic Acids and Polypeptides**

One aspect of the invention pertains to isolated nucleic acid molecules that encode NOVX polypeptides or biologically active portions thereof. Also included in the invention are nucleic acid fragments sufficient for use as hybridization probes to identify NOVX-encoding nucleic acids (e.g., NOVX mRNAs) and fragments for use as PCR primers for the amplification and/or mutation of NOVX nucleic acid molecules. As used herein, the term "nucleic acid molecule" is intended to include DNA molecules (e.g., cDNA or genomic DNA), RNA molecules (e.g., mRNA), analogs of the DNA or RNA generated using nucleotide analogs, and derivatives, fragments and homologs thereof. The nucleic acid molecule may be single-stranded or double-stranded, but preferably is comprised of double-stranded DNA.

A NOVX nucleic acid can encode a mature NOVX polypeptide. As used herein, a "mature" form of a polypeptide or protein disclosed in the present invention is the product of a naturally occurring polypeptide or precursor form or proprotein. The naturally occurring polypeptide, precursor or proprotein includes, by way of nonlimiting example, the full-length gene product encoded by the corresponding gene. Alternatively, it may be defined as the polypeptide, precursor or proprotein encoded by an ORF described herein. The product "mature" form arises, by way of nonlimiting example, as a result of one or more naturally occurring processing steps that may take place within the cell (e.g., host cell) in which the gene product arises. Examples of such processing steps leading to a "mature" form of a polypeptide or protein include the cleavage of the N-terminal methionine residue encoded by the initiation codon of an ORF, or the proteolytic cleavage of a signal peptide or leader sequence. Thus a mature form arising from a precursor polypeptide or protein that has residues 1 to N, where residue 1 is the N-terminal methionine, would have residues 2 through N remaining after removal of the N-terminal methionine. Alternatively, a mature form arising from a precursor polypeptide or protein having residues 1 to N,

in which an N-terminal signal sequence from residue 1 to residue M is cleaved, would have the residues from residue M+1 to residue N remaining. Further as used herein, a "mature" form of a polypeptide or protein may arise from a step of post-translational modification other than a proteolytic cleavage event. Such additional processes include, by way of non-limiting example, glycosylation, myristylation or phosphorylation. In general, a mature polypeptide or protein may result from the operation of only one of these processes, or a combination of any of them.

The term "probe", as utilized herein, refers to nucleic acid sequences of variable length, preferably between at least about 10 nucleotides (nt), about 100 nt, or as many as approximately 6,000 nt, depending upon the specific use. Probes are used in the detection of identical, similar, or complementary nucleic acid sequences. Longer length probes are generally obtained from a natural or recombinant source, are highly specific, and much slower to hybridize than shorter-length oligomer probes. Probes may be single- stranded or double-stranded and designed to have specificity in PCR, membrane-based hybridization technologies, or ELISA-like technologies.

The term "isolated" nucleic acid molecule, as used herein, is a nucleic acid that is separated from other nucleic acid molecules which are present in the natural source of the nucleic acid. Preferably, an "isolated" nucleic acid is free of sequences which naturally flank the nucleic acid (*i.e.*, sequences located at the 5'- and 3'-termini of the nucleic acid) in the genomic DNA of the organism from which the nucleic acid is derived. For example, in various embodiments, the isolated NOVX nucleic acid molecules can contain less than about 5 kb, 4 kb, 3 kb, 2 kb, 1 kb, 0.5 kb or 0.1 kb of nucleotide sequences which naturally flank the nucleic acid molecule in genomic DNA of the cell/tissue from which the nucleic acid is derived (*e.g.*, brain, heart, liver, spleen, *etc.*). Moreover, an "isolated" nucleic acid molecule, such as a cDNA molecule, can be substantially free of other cellular material, or culture medium, or of chemical precursors or other chemicals.

A nucleic acid molecule of the invention, *e.g.*, a nucleic acid molecule having the nucleotide sequence of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, or a complement of this nucleotide sequence, can be isolated using standard molecular biology techniques and the sequence information provided herein. Using all or a portion of the nucleic acid sequence of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, as a hybridization probe, NOVX molecules can be isolated using standard hybridization and cloning techniques (*e.g.*, as described in Sambrook, *et al.*, (eds.), MOLECULAR CLONING: A LABORATORY MANUAL 2<sup>nd</sup> Ed., Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1989; and Ausubel, *et al.*, (eds.), CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, New York, NY, 1993.)

A nucleic acid of the invention can be amplified using cDNA, mRNA or alternatively, genomic DNA, as a template with appropriate oligonucleotide primers according to standard PCR amplification techniques. The nucleic acid so amplified can be cloned into an appropriate vector and characterized by DNA sequence analysis. Furthermore, oligonucleotides corresponding to NOVX nucleotide sequences can be prepared by standard synthetic techniques, *e.g.*, using an automated DNA synthesizer.

As used herein, the term "oligonucleotide" refers to a series of linked nucleotide residues. A short oligonucleotide sequence may be based on, or designed from, a genomic or cDNA sequence and is used to amplify, confirm, or reveal the presence of an identical, similar or complementary DNA or RNA in a particular cell or tissue. Oligonucleotides comprise a nucleic acid sequence having about 10 nt, 50 nt, or 100 nt in length, preferably about 15 nt to 30 nt in length. In one embodiment of the invention, an oligonucleotide comprising a nucleic acid molecule less than 100 nt in length would further comprise at least 6 contiguous nucleotides of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, or a complement thereof. Oligonucleotides may be chemically synthesized and may also be used as probes.

In another embodiment, an isolated nucleic acid molecule of the invention comprises a nucleic acid molecule that is a complement of the nucleotide sequence shown in SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, or a portion of this nucleotide sequence (e.g., a fragment that can be used as a probe or primer or a fragment encoding a biologically-active portion of a NOVX polypeptide). A nucleic acid molecule that is complementary to the nucleotide sequence of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, is one that is sufficiently complementary to the nucleotide sequence of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, that it can hydrogen bond with few or no mismatches to the nucleotide sequence shown in SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, thereby forming a stable duplex.

As used herein, the term "complementary" refers to Watson-Crick or Hoogsteen base pairing between nucleotides units of a nucleic acid molecule, and the term "binding" means the physical or chemical interaction between two polypeptides or compounds or associated polypeptides or compounds or combinations thereof. Binding includes ionic, non-ionic, van der Waals, hydrophobic interactions, and the like. A physical interaction can be either direct or indirect. Indirect interactions may be through or due to the effects of another polypeptide or compound. Direct binding refers to interactions that do not take place through, or due to, the effect of another polypeptide or compound, but instead are without other substantial chemical intermediates.

A "fragment" provided herein is defined as a sequence of at least 6 (contiguous) nucleic acids or at least 4 (contiguous) amino acids, a length sufficient to allow for specific hybridization in the case of nucleic acids or for specific recognition of an epitope in the case of amino acids, and is at most some portion less than a full length sequence. Fragments may be derived from any contiguous portion of a nucleic acid or amino acid sequence of choice.

A full-length NOVX clone is identified as containing an ATG translation start codon and an in-frame stop codon. Any disclosed NOVX nucleotide sequence lacking an ATG start codon therefore encodes a truncated C-terminal fragment of the respective NOVX polypeptide, and requires that the corresponding full-length cDNA extend in the 5' direction of the disclosed sequence. Any disclosed NOVX nucleotide sequence lacking an in-frame stop codon similarly encodes a truncated N-terminal fragment of the respective NOVX polypeptide, and requires that the corresponding full-length cDNA extend in the 3' direction of the disclosed sequence.

A "derivative" is a nucleic acid sequence or amino acid sequence formed from the native compounds either directly, by modification or partial substitution. An "analog" is a nucleic acid sequence or amino acid sequence that has a structure similar to, but not identical to, the native compound, e.g. they differs from it in respect to certain components or side chains. Analogs may be synthetic or derived from a different evolutionary origin and may have a similar or opposite metabolic activity compared to wild type. A "homolog" is a nucleic acid sequence or amino acid sequence of a particular gene that is derived from different species.

Derivatives and analogs may be full length or other than full length. Derivatives or analogs of the nucleic acids or proteins of the invention include, but are not limited to, molecules comprising regions that are substantially homologous to the nucleic acids or proteins of the invention, in various embodiments, by at least about 70%, 80%, or 95%, or more identity, with a preferred identity of 80-95%, and most preferred identity of 98-99% or more, over a nucleic acid or amino acid sequence of identical size or when compared to an aligned sequence in which the alignment is done by a computer homology program known in the art, or whose encoding nucleic acid is capable of hybridizing to the complement of a sequence encoding the proteins under stringent, moderately stringent, or low stringent conditions. See e.g. Ausubel, *et al.*, CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, New York, NY, 1993, and below.

A "homologous nucleic acid sequence" or "homologous amino acid sequence," or variations thereof, refer to sequences characterized by a homology at the nucleotide level or amino acid level as discussed above. Homologous nucleotide sequences include those sequences coding for isoforms of NOVX polypeptides. Isoforms can be expressed in different tissues of the same organism as a result of, for example, alternative splicing of RNA. Alternatively, isoforms can be encoded by different genes. In the invention, homologous nucleotide sequences include nucleotide sequences encoding for a NOVX polypeptide of species other than humans, including, but not limited to: vertebrates, and thus can include, e.g., frog, mouse, rat, rabbit, dog, cat, cow, horse, and other organisms. Homologous nucleotide sequences also include, but are not limited to, naturally occurring allelic variations and mutations of the nucleotide sequences set forth herein. A homologous nucleotide sequence does not, however, include the exact nucleotide sequence encoding human NOVX protein. Homologous nucleic acid sequences include those nucleic acid sequences that encode conservative amino acid substitutions (see below) in SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, as well as a polypeptide possessing NOVX biological activity. Various biological activities of the NOVX proteins are described below.

A NOVX polypeptide is encoded by the open reading frame ("ORF") of a NOVX nucleic acid. An ORF corresponds to a nucleotide sequence that could potentially be translated into a polypeptide. A stretch of nucleic acids comprising an ORF is uninterrupted by a stop codon. An ORF that represents the coding sequence for a full protein begins with an ATG "start" codon and terminates with one of the three "stop" codons, namely, TAA, TAG, or TGA. For the purposes of this invention, an ORF may be any part of a coding sequence, with or without a start codon, a stop codon, or both. For an ORF to be considered as a good candidate for coding for a *bona fide*

cellular protein, a minimum size requirement is often set, e.g., a stretch of DNA that would encode a protein of 50 amino acids or more.

The nucleotide sequences determined from the cloning of the human NOVX genes allows for the generation of probes and primers designed for use in identifying and/or cloning NOVX homologues in other cell types, e.g. from other tissues, as well as NOVX homologues from other vertebrates. The probe/primer typically comprises substantially purified oligonucleotide. The oligonucleotide typically comprises a region of nucleotide sequence that hybridizes under stringent conditions to at least about 12, 25, 50, 100, 150, 200, 250, 300, 350 or 400 consecutive sense strand nucleotide sequence of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71; or an anti-sense strand nucleotide sequence of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71; or of a naturally occurring mutant of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71.

Probes based on the human NOVX nucleotide sequences can be used to detect transcripts or genomic sequences encoding the same or homologous proteins. In various embodiments, the probe has a detectable label attached, e.g. the label can be a radioisotope, a fluorescent compound, an enzyme, or an enzyme co-factor. Such probes can be used as a part of a diagnostic test kit for identifying cells or tissues which mis-express a NOVX protein, such as by measuring a level of a NOVX-encoding nucleic acid in a sample of cells from a subject e.g., detecting NOVX mRNA levels or determining whether a genomic NOVX gene is up or down regulated or has been mutated or deleted.

"A polypeptide having a biologically-active portion of a NOVX polypeptide" refers to polypeptides exhibiting activity similar, but not necessarily identical to, an activity of a polypeptide of the invention, including mature forms, as measured in a particular biological assay, with or without dose dependency. A nucleic acid fragment encoding a "biologically-active portion of NOVX" can be prepared by isolating a portion of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, that encodes a polypeptide having a NOVX biological activity (the biological activities of the NOVX proteins are described below), expressing the encoded portion of NOVX protein (e.g., by recombinant expression *in vitro*) and assessing the activity of the encoded portion of NOVX.

### **NOVX Single Nucleotide Polymorphisms**

Variant sequences are also included in this application. A variant sequence can include a single nucleotide polymorphism (SNP). A SNP can, in some instances, be referred to as a "cSNP" to denote that the nucleotide sequence containing the SNP originates as a cDNA. SNPs occurring within genes may result in an alteration of the amino acid encoded by the gene at the position of the SNP. Preferred embodiments include NOV1b, NOV1c, NOV1d, NOV1e, NOV1f, NOV1g, NOV1h, NOV1i, NOV1j, NOV1k, NOV1l, NOV1m, NOV1n, NOV1o, NOV1p, NOV1q, NOV1r, NOV1s, NOV1t, NOV6c, NOV6d, NOV6e, NOV6f, NOV6g, NOV6h, NOV6i, NOV6j, NOV6k, NOV6l, NOV8b, NOV8c, NOV8d, NOV8e, NOV8f, and NOV9h.

## NOVX Nucleic Acid and Polypeptide Variants

The invention further encompasses nucleic acid molecules that differ from the nucleotide sequences of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, due to degeneracy of the genetic code and thus encode the same NOVX proteins as that encoded by the nucleotide sequences of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71. In another embodiment, an isolated nucleic acid molecule of the invention has a nucleotide sequence encoding a protein having an amino acid sequence of SEQ ID NO:2*n*, wherein *n* is an integer between 1 and 71 or is 94.

In addition to the human NOVX nucleotide sequences of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, it will be appreciated by those skilled in the art that DNA sequence polymorphisms that lead to changes in the amino acid sequences of the NOVX polypeptides may exist within a population (e.g., the human population). Such genetic polymorphism in the NOVX genes may exist among individuals within a population due to natural allelic variation. As used herein, the terms "gene" and "recombinant gene" refer to nucleic acid molecules comprising an open reading frame (ORF) encoding a NOVX protein, preferably a vertebrate NOVX protein. Such natural allelic variations can typically result in 1-5% variance in the nucleotide sequence of the NOVX genes. Any and all such nucleotide variations and resulting amino acid polymorphisms in the NOVX polypeptides, which are the result of natural allelic variation and that do not alter the functional activity of the NOVX polypeptides, are intended to be within the scope of the invention.

Moreover, nucleic acid molecules encoding NOVX proteins from other species, and thus that have a nucleotide sequence that differs from a human SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, are intended to be within the scope of the invention. Nucleic acid molecules corresponding to natural allelic variants and homologues of the NOVX cDNAs of the invention can be isolated based on their homology to the human NOVX nucleic acids disclosed herein using the human cDNAs, or a portion thereof, as a hybridization probe according to standard hybridization techniques under stringent hybridization conditions.

Accordingly, in another embodiment, an isolated nucleic acid molecule of the invention is at least 6 nucleotides in length and hybridizes under stringent conditions to the nucleic acid molecule comprising the nucleotide sequence of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71. In another embodiment, the nucleic acid is at least 10, 25, 50, 100, 250, 500, 750, 1000, 1500, or 2000 or more nucleotides in length. In yet another embodiment, an isolated nucleic acid molecule of the invention hybridizes to the coding region. Homologs (*i.e.*, nucleic acids encoding NOVX proteins derived from species other than human) or other related sequences (e.g., paralogs) can be obtained by low, moderate or high stringency hybridization with all or a portion of the particular human sequence as a probe using methods well known in the art for nucleic acid hybridization and cloning.

As used herein, the phrase "stringent hybridization conditions" refers to conditions under which a probe, primer or oligonucleotide will hybridize to its target sequence, but to no other sequences. Stringent conditions are sequence-dependent and will be different in different

circumstances. Longer sequences hybridize specifically at higher temperatures than shorter sequences. Generally, stringent conditions are selected to be about 5 °C lower than the thermal melting point ( $T_m$ ) for the specific sequence at a defined ionic strength and pH. The  $T_m$  is the temperature (under defined ionic strength, pH and nucleic acid concentration) at which 50% of the probes complementary to the target sequence hybridize to the target sequence at equilibrium. Since the target sequences are generally present at excess, at  $T_m$ , 50% of the probes are occupied at equilibrium. Typically, stringent conditions will be those in which the salt concentration is less than about 1.0 M sodium ion, typically about 0.01 to 1.0 M sodium ion (or other salts) at pH 7.0 to 8.3 and the temperature is at least about 30 °C for short probes, primers or oligonucleotides (e.g., 10 nt to 50 nt) and at least about 60 °C for longer probes, primers and oligonucleotides. Stringent conditions may also be achieved with the addition of destabilizing agents, such as formamide.

Stringent conditions are known to those skilled in the art and can be found in Ausubel, *et al.*, (eds.), CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, N.Y. (1989), 6.3.1-6.3.6. Preferably, the conditions are such that sequences at least about 65%, 70%, 75%, 85%, 90%, 95%, 98%, or 99% homologous to each other typically remain hybridized to each other. A non-limiting example of stringent hybridization conditions are hybridization in a high salt buffer comprising 6X SSC, 50 mM Tris-HCl (pH 7.5), 1 mM EDTA, 0.02% PVP, 0.02% Ficoll, 0.02% BSA, and 500 mg/ml denatured salmon sperm DNA at 65°C, followed by one or more washes in 0.2X SSC, 0.01% BSA at 50°C. An isolated nucleic acid molecule of the invention that hybridizes under stringent conditions to a sequence of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, corresponds to a naturally-occurring nucleic acid molecule. As used herein, a "naturally-occurring" nucleic acid molecule refers to an RNA or DNA molecule having a nucleotide sequence that occurs in nature (e.g., encodes a natural protein).

In a second embodiment, a nucleic acid sequence that is hybridizable to the nucleic acid molecule comprising the nucleotide sequence of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, or fragments, analogs or derivatives thereof, under conditions of moderate stringency is provided. A non-limiting example of moderate stringency hybridization conditions are hybridization in 6X SSC, 5X Reinhardt's solution, 0.5% SDS and 100 mg/ml denatured salmon sperm DNA at 55 °C, followed by one or more washes in 1X SSC, 0.1% SDS at 37 °C. Other conditions of moderate stringency that may be used are well-known within the art. See, e.g., Ausubel, *et al.* (eds.), 1993, CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, NY, and Krieger, 1990; GENE TRANSFER AND EXPRESSION, A LABORATORY MANUAL, Stockton Press, NY.

In a third embodiment, a nucleic acid that is hybridizable to the nucleic acid molecule comprising the nucleotide sequences of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, or fragments, analogs or derivatives thereof, under conditions of low stringency, is provided. A non-limiting example of low stringency hybridization conditions are hybridization in 35% formamide, 5X SSC, 50 mM Tris-HCl (pH 7.5), 5 mM EDTA, 0.02% PVP, 0.02% Ficoll, 0.2% BSA, 100 mg/ml denatured salmon sperm DNA, 10% (wt/vol) dextran sulfate at 40°C, followed by one or more washes in 2X SSC, 25 mM Tris-HCl (pH 7.4), 5 mM EDTA, and 0.1% SDS at 50°C. Other

conditions of low stringency that may be used are well known in the art (e.g., as employed for cross-species hybridizations). See, e.g., Ausubel, *et al.* (eds.), 1993, CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, NY, and Kriegler, 1990, GENE TRANSFER AND EXPRESSION, A LABORATORY MANUAL, Stockton Press, NY; *Proc Natl Acad Sci USA* **78**: 6789-6792 (1981).

### Conservative Mutations

In addition to naturally-occurring allelic variants of NOVX sequences that may exist in the population, the skilled artisan will further appreciate that changes can be introduced by mutation into the nucleotide sequences of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, thereby leading to changes in the amino acid sequences of the encoded NOVX protein, without altering the functional ability of that NOVX protein. For example, nucleotide substitutions leading to amino acid substitutions at "non-essential" amino acid residues can be made in the sequence of SEQ ID NO:2*n*, wherein *n* is an integer between 1 and 71 or is 94. A "non-essential" amino acid residue is a residue that can be altered from the wild-type sequences of the NOVX proteins without altering their biological activity, whereas an "essential" amino acid residue is required for such biological activity. For example, amino acid residues that are conserved among the NOVX proteins of the invention are predicted to be particularly non-amenable to alteration. Amino acids for which conservative substitutions can be made are well-known within the art.

Another aspect of the invention pertains to nucleic acid molecules encoding NOVX proteins that contain changes in amino acid residues that are not essential for activity. Such NOVX proteins differ in amino acid sequence from SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, yet retain biological activity. In one embodiment, the isolated nucleic acid molecule comprises a nucleotide sequence encoding a protein, wherein the protein comprises an amino acid sequence at least about 80% homologous to SEQ ID NO:2*n*, wherein *n* is an integer between 1 and 71 or is 94; more preferably at least about 90% homologous, even more preferably at least about 95% homologous, most preferably 98-99% homologous to SEQ ID NO:2*n*, wherein *n* is an integer between 1 and 71 or is 94.

An isolated nucleic acid molecule encoding a NOVX protein homologous to the protein of SEQ ID NO:2*n*, wherein *n* is an integer between 1 and 71 or is 94, can be created by introducing one or more nucleotide substitutions, additions or deletions into the nucleotide sequence of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, such that one or more amino acid substitutions, additions or deletions are introduced into the encoded protein.

Mutations can be introduced any one of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, by standard techniques, such as site-directed mutagenesis and PCR-mediated mutagenesis. Preferably, conservative amino acid substitutions are made at one or more predicted, non-essential amino acid residues. A "conservative amino acid substitution" is one in which the amino acid residue is replaced with an amino acid residue having a similar side chain. Families of amino acid residues having similar side chains have been defined within the art. These families include amino acids with basic side chains (e.g., lysine, arginine, histidine), acidic

side chains (e.g., aspartic acid, glutamic acid), uncharged polar side chains (e.g., glycine, asparagine, glutamine, serine, threonine, tyrosine, cysteine), nonpolar side chains (e.g., alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine, tryptophan), beta-branched side chains (e.g., threonine, valine, isoleucine) and aromatic side chains (e.g., tyrosine, phenylalanine, tryptophan, histidine). Thus, a predicted non-essential amino acid residue in the NOVX protein is replaced with another amino acid residue from the same side chain family. Alternatively, in another embodiment, mutations can be introduced randomly along all or part of a NOVX coding sequence, such as by saturation mutagenesis, and the resultant mutants can be screened for NOVX biological activity to identify mutants that retain activity. Following mutagenesis of a nucleic acid of SEQ ID NO:2*n*-1, wherein *n* is an integer between 1 and 71, the encoded protein can be expressed by any recombinant technology known in the art and the activity of the protein can be determined.

The relatedness of amino acid families may also be determined based on side chain interactions. Substituted amino acids may be fully conserved "strong" residues or fully conserved "weak" residues. The "strong" group of conserved amino acid residues may be any one of the following groups: STA, NEQK, NHQK, NDEQ, QHRK, MILV, MILF, HY, FYW, wherein the single letter amino acid codes are grouped by those amino acids that may be substituted for each other. Likewise, the "weak" group of conserved residues may be any one of the following: CSA, ATV, SAG, STNK, STPA, SGND, SNDEQK, NDEQHK, NEQHRK, HFY, wherein the letters within each group represent the single letter amino acid code.

In one embodiment, a mutant NOVX protein can be assayed for (i) the ability to form protein:protein interactions with other NOVX proteins, other cell-surface proteins, or biologically-active portions thereof, (ii) complex formation between a mutant NOVX protein and a NOVX ligand; or (iii) the ability of a mutant NOVX protein to bind to an intracellular target protein or biologically-active portion thereof; (e.g. avidin proteins).

In yet another embodiment, a mutant NOVX protein can be assayed for the ability to regulate a specific biological function (e.g., regulation of insulin release).

### **Interfering RNA**

In one aspect of the invention, NOVX gene expression can be attenuated by RNA interference. One approach well-known in the art is short interfering RNA (siRNA) mediated gene silencing where expression products of a NOVX gene are targeted by specific double stranded NOVX derived siRNA nucleotide sequences that are complementary to at least a 19-25 nt long segment of the NOVX gene transcript, including the 5' untranslated (UT) region, the ORF, or the 3' UT region. See, e.g., PCT applications WO00/44895, WO99/32619, WO01/75164, WO01/92513, WO 01/29058, WO01/89304, WO02/16620, and WO02/29858, each incorporated by reference herein in their entirety. Targeted genes can be a NOVX gene, or an upstream or downstream modulator of the NOVX gene. Nonlimiting examples of upstream or downstream modulators of a NOVX gene include, e.g., a transcription factor that binds the NOVX gene promoter, a kinase or

phosphatase that interacts with a NOVX polypeptide, and polypeptides involved in a NOVX regulatory pathway.

An inventive therapeutic method of the invention contemplates administering a NOVX siRNA construct as therapy to compensate for increased or aberrant NOVX expression or activity.

5 The NOVX ribopolynucleotide is obtained and processed into siRNA fragments, or a NOVX siRNA is synthesized, as described above. The NOVX siRNA is administered to cells or tissues using known nucleic acid transfection techniques, as described above. A NOVX siRNA specific for a NOVX gene will decrease or knockdown NOVX transcription products, which will lead to reduced NOVX polypeptide production, resulting in reduced NOVX polypeptide activity in the cells or  
10 tissues.

The present invention also encompasses a method of treating a disease or condition associated with the presence of a NOVX protein in an individual comprising administering to the individual an RNAi construct that targets the mRNA of the protein (the mRNA that encodes the protein) for degradation. A specific RNAi construct includes a siRNA or a double stranded gene  
15 transcript that is processed into siRNAs. Upon treatment, the target protein is not produced or is not produced to the extent it would be in the absence of the treatment.

In specific embodiments, a NOVX siRNA is used in therapy. Methods for the generation and use of a NOVX siRNA are known to those skilled in the art. Example techniques are provided below.

## 20 **Production of RNAs**

Sense RNA (ssRNA) and antisense RNA (asRNA) of NOVX are produced using known methods such as transcription in RNA expression vectors. In the initial experiments, the sense and antisense RNA are about 500 bases in length each. The produced ssRNA and asRNA (0.5  $\mu$ M) in 10 mM Tris-HCl (pH 7.5) with 20 mM NaCl were heated to 95° C for 1 min then cooled  
25 and annealed at room temperature for 12 to 16 h. The RNAs are precipitated and resuspended in lysis buffer (below). To monitor annealing, RNAs are electrophoresed in a 2% agarose gel in TBE buffer and stained with ethidium bromide. See, e.g., Sambrook et al., Molecular Cloning. Cold Spring Harbor Laboratory Press, Plainview, N.Y. (1989).

## **Lysate Preparation**

30 Untreated rabbit reticulocyte lysate (Ambion) are assembled according to the manufacturer's directions. dsRNA is incubated in the lysate at 30° C for 10 min prior to the addition of mRNAs. Then NOVX mRNAs are added and the incubation continued for an additional 60 min. The molar ratio of double stranded RNA and mRNA is about 200:1. The NOVX mRNA is radiolabeled (using known techniques) and its stability is monitored by gel electrophoresis.

35 In a parallel experiment made with the same conditions, the double stranded RNA is internally radiolabeled with a <sup>32</sup>P-ATP. Reactions are stopped by the addition of 2 X proteinase K buffer and deproteinized as described previously (Genes Dev., 13:3191-3197, 1999). Products are analyzed by electrophoresis in 15% or 18% polyacrylamide sequencing gels using appropriate

RNA standards. By monitoring the gels for radioactivity, the natural production of 10 to 25 nt RNAs from the double stranded RNA can be determined.

The band of double stranded RNA, about 21-23 bps, is eluted. The efficacy of these 21-23 mers for suppressing NOVX transcription is assayed in vitro using the same rabbit reticulocyte assay described above using 50 nanomolar of double stranded 21-23 mer for each assay. The sequence of these 21-23 mers is then determined using standard nucleic acid sequencing techniques.

### RNA Preparation

21 nt RNAs, based on the sequence determined above, are chemically synthesized using Expedite RNA phosphoramidites and thymidine phosphoramidite (Proligo, Germany). Synthetic oligonucleotides are deprotected and gel-purified (Genes & Dev. 15, 188-200, 2001), followed by Sep-Pak C18 cartridge (Waters, Milford, Mass., USA) purification (Biochemistry, 32:11658-11668 1993).

These RNAs (20  $\mu$ M) single strands are incubated in annealing buffer (100 mM potassium acetate, 30 mM HEPES-KOH at pH 7.4, 2 mM magnesium acetate) for 1 min at 90° C followed by 1 h at 37° C.

### Cell Culture

A cell culture known in the art to regularly express NOVX is propagated using standard conditions. 24 hours before transfection, at approx. 80% confluency, the cells are trypsinized and diluted 1:5 with fresh medium without antibiotics ( $1-3 \times 10^5$  cells/ml) and transferred to 24-well plates (500  $\mu$ l/well). Transfection is performed using a commercially available lipofection kit and NOVX expression is monitored using standard techniques with positive and negative control. A positive control is cells that naturally express NOVX while a negative control is cells that do not express NOVX. Base-paired 21 and 22 nt siRNAs with overhanging 3' ends mediate efficient sequence-specific mRNA degradation in lysates and in cell culture. Different concentrations of siRNAs are used. An efficient concentration for suppression in vitro in mammalian culture is between 25 nM to 100 nM final concentration. This indicates that siRNAs are effective at concentrations that are several orders of magnitude below the concentrations applied in conventional antisense or ribozyme gene targeting experiments.

The above method provides a way both for the deduction of NOVX siRNA sequence and the use of such siRNA for in vitro suppression. In vivo suppression may be performed using the same siRNA using well known in vivo transfection or gene therapy transfection techniques.

### Antisense Nucleic Acids

Another aspect of the invention pertains to isolated antisense nucleic acid molecules that are hybridizable to or complementary to the nucleic acid molecule comprising the nucleotide sequence of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, or fragments, analogs or derivatives thereof. An "antisense" nucleic acid comprises a nucleotide sequence that is

complementary to a "sense" nucleic acid encoding a protein (e.g., complementary to the coding strand of a double-stranded cDNA molecule or complementary to an mRNA sequence). In specific aspects, antisense nucleic acid molecules are provided that comprise a sequence complementary to at least about 10, 25, 50, 100, 250 or 500 nucleotides or an entire NOVX coding strand, or to only a portion thereof. Nucleic acid molecules encoding fragments, homologs, derivatives and analogs of a NOVX protein of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, or antisense nucleic acids complementary to a NOVX nucleic acid sequence of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71, are additionally provided.

In one embodiment, an antisense nucleic acid molecule is antisense to a "coding region" of the coding strand of a nucleotide sequence encoding a NOVX protein. The term "coding region" refers to the region of the nucleotide sequence comprising codons which are translated into amino acid residues. In another embodiment, the antisense nucleic acid molecule is antisense to a "noncoding region" of the coding strand of a nucleotide sequence encoding the NOVX protein. The term "noncoding region" refers to 5' and 3' sequences which flank the coding region that are not translated into amino acids (*i.e.*, also referred to as 5' and 3' untranslated regions).

Given the coding strand sequences encoding the NOVX protein disclosed herein, antisense nucleic acids of the invention can be designed according to the rules of Watson and Crick or Hoogsteen base pairing. The antisense nucleic acid molecule can be complementary to the entire coding region of NOVX mRNA, but more preferably is an oligonucleotide that is antisense to only a portion of the coding or noncoding region of NOVX mRNA. For example, the antisense oligonucleotide can be complementary to the region surrounding the translation start site of NOVX mRNA. An antisense oligonucleotide can be, for example, about 5, 10, 15, 20, 25, 30, 35, 40, 45 or 50 nucleotides in length. An antisense nucleic acid of the invention can be constructed using chemical synthesis or enzymatic ligation reactions using procedures known in the art. For example, an antisense nucleic acid (e.g., an antisense oligonucleotide) can be chemically synthesized using naturally-occurring nucleotides or variously modified nucleotides designed to increase the biological stability of the molecules or to increase the physical stability of the duplex formed between the antisense and sense nucleic acids (e.g., phosphorothioate derivatives and acridine substituted nucleotides can be used).

Examples of modified nucleotides that can be used to generate the antisense nucleic acid include: 5-fluorouracil, 5-bromouracil, 5-chlorouracil, 5-iodouracil, hypoxanthine, xanthine, 4-acetylcytosine, 5-carboxymethylaminomethyl-2-thiouridine, 5-(carboxyhydroxymethyl) uracil, 5-carboxymethylaminomethyluracil, dihydrouracil, beta-D-galactosylqueosine, inosine, N6-isopentenyladenine, 1-methylguanine, 1-methylinosine, 2,2-dimethylguanine, 2-methyladenine, 2-methylguanine, 5-methoxyuracil, 3-methylcytosine, 5-methylcytosine, N6-adenine, 7-methylguanine, 5-methylaminomethyluracil, 5-methoxyaminomethyl-2-thiouracil, 2-thiouracil, 4-thiouracil, beta-D-mannosylqueosine, 5'-methoxycarboxymethyluracil, 2-methylthio-N6-isopentenyladenine, uracil-5-oxyacetic acid (v), wybutoxosine, pseudouracil, queosine, 2-thiocytosine, 5-methyl-2-thiouracil, 5-methyluracil, uracil-5-oxyacetic acid methylester, uracil-5-oxyacetic acid (v), 5-methyl-2-thiouracil, 3-(3-amino-3-N-2-carboxypropyl) uracil, (acp3)w,

and 2,6-diaminopurine. Alternatively, the antisense nucleic acid can be produced biologically using an expression vector into which a nucleic acid has been subcloned in an antisense orientation (*i.e.*, RNA transcribed from the inserted nucleic acid will be of an antisense orientation to a target nucleic acid of interest, described further in the following subsection).

5           The antisense nucleic acid molecules of the invention are typically administered to a subject or generated *in situ* such that they hybridize with or bind to cellular mRNA and/or genomic DNA encoding a NOVX protein to thereby inhibit expression of the protein (*e.g.*, by inhibiting transcription and/or translation). The hybridization can be by conventional nucleotide complementarity to form a stable duplex, or, for example, in the case of an antisense nucleic acid molecule that binds to DNA duplexes, through specific interactions in the major groove of the double helix. An example of a route of administration of antisense nucleic acid molecules of the invention includes direct injection at a tissue site. Alternatively, antisense nucleic acid molecules can be modified to target selected cells and then administered systemically. For example, for systemic administration, antisense molecules can be modified such that they specifically bind to receptors or antigens expressed on a selected cell surface (*e.g.*, by linking the antisense nucleic acid molecules to peptides or antibodies that bind to cell surface receptors or antigens). The antisense nucleic acid molecules can also be delivered to cells using the vectors described herein. To achieve sufficient nucleic acid molecules, vector constructs in which the antisense nucleic acid molecule is placed under the control of a strong pol II or pol III promoter are preferred.

20           In yet another embodiment, the antisense nucleic acid molecule of the invention is an  $\alpha$ -anomeric nucleic acid molecule. An  $\alpha$ -anomeric nucleic acid molecule forms specific double-stranded hybrids with complementary RNA in which, contrary to the usual  $\beta$ -units, the strands run parallel to each other. See, *e.g.*, *Nucl. Acids Res.* **15**: 6625-6641 (1987). The antisense nucleic acid molecule can also comprise a 2'-*o*-methylribonucleotide (See, *e.g.*, *Nucl. Acids Res.* **15**: 6131-6148, 1987) or a chimeric RNA-DNA analogue (See, *e.g.*, *FEBS Lett.* **215**: 327-330, 1987).

### **Ribozymes and PNA Moieties**

30           Nucleic acid modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject.

35           In one embodiment, an antisense nucleic acid of the invention is a ribozyme. Ribozymes are catalytic RNA molecules with ribonuclease activity that are capable of cleaving a single-stranded nucleic acid, such as an mRNA, to which they have a complementary region. Thus, ribozymes (*e.g.*, hammerhead ribozymes as described in *Nature* **334**: 585-591, 1988) can be used to catalytically cleave NOVX mRNA transcripts to thereby inhibit translation of NOVX mRNA. A ribozyme having specificity for a NOVX-encoding nucleic acid can be designed based upon the nucleotide sequence of a NOVX cDNA disclosed herein (*i.e.*, SEQ ID NO:2*n*-1, wherein *n* is an

integer between 1 and 71). For example, a derivative of a *Tetrahymena* L-19 IVS RNA can be constructed in which the nucleotide sequence of the active site is complementary to the nucleotide sequence to be cleaved in a NOVX-encoding mRNA. See, e.g., U.S. Patent 4,987,071; U.S. Patent 5,116,742. NOVX mRNA can also be used to select a catalytic RNA having a specific ribonuclease activity from a pool of RNA molecules. See, e.g., Science 261:1411-1418 (1993).

Alternatively, NOVX gene expression can be inhibited by targeting nucleotide sequences complementary to the regulatory region of the NOVX nucleic acid (e.g., the NOVX promoter and/or enhancers) to form triple helical structures that prevent transcription of the NOVX gene in target cells. See, e.g., Anticancer Drug Des. 6: 569-84,1991; Ann. N.Y. Acad. Sci. 660: 27-36,1992; Bioassays 14: 807-15,1992.

In various embodiments, the NOVX nucleic acids can be modified at the base moiety, sugar moiety or phosphate backbone to improve, e.g., the stability, hybridization, or solubility of the molecule. For example, the deoxyribose phosphate backbone of the nucleic acids can be modified to generate peptide nucleic acids. See, e.g., Bioorg Med Chem 4: 5-23,1996. As used herein, the terms "peptide nucleic acids" or "PNAs" refer to nucleic acid mimics (e.g., DNA mimics) in which the deoxyribose phosphate backbone is replaced by a pseudopeptide backbone and only the four natural nucleotide bases are retained. The neutral backbone of PNAs has been shown to allow for specific hybridization to DNA and RNA under conditions of low ionic strength. The synthesis of PNA oligomer can be performed using standard solid phase peptide synthesis protocols as described in Bioorg Med Chem 4: 5-23,1996; Proc. Natl. Acad. Sci. USA 93: 14670-14675, 1996.

PNAs of NOVX can be used in therapeutic and diagnostic applications. For example, PNAs can be used as antisense or antigene agents for sequence-specific modulation of gene expression by, e.g., inducing transcription or translation arrest or inhibiting replication. PNAs of NOVX can also be used, for example, in the analysis of single base pair mutations in a gene (e.g., PNA directed PCR clamping; as artificial restriction enzymes when used in combination with other enzymes, e.g., S<sub>1</sub> nucleases (See, Bioorg Med Chem 4: 5-23,1996); or as probes or primers for DNA sequence and hybridization (See, Bioorg Med Chem 4: 5-23,1996; Proc. Natl. Acad. Sci. USA 93: 14670-14675, 1996).

In other embodiments, the oligonucleotide may include other appended groups such as peptides (e.g., for targeting host cell receptors *in vivo*), or agents facilitating transport across the cell membrane (see, e.g., Proc. Natl. Acad. Sci. U.S.A. 86: 6553-6556,1989; Proc. Natl. Acad. Sci. 84: 648-652,1987; PCT Publication No. WO88/09810) or the blood-brain barrier (see, e.g., PCT Publication No. WO 89/10134). In addition, oligonucleotides can be modified with hybridization triggered cleavage agents (see, e.g., BioTechniques 6:958-976,1988) or intercalating agents (see, e.g., Pharm. Res. 5: 539-549,1988). To this end, the oligonucleotide may be conjugated to another molecule, e.g., a peptide, a hybridization triggered cross-linking agent, a transport agent, a hybridization-triggered cleavage agent, and the like.

## NOVX Polypeptides

A polypeptide according to the invention includes a polypeptide of the amino acid sequence of NOVX polypeptides whose sequences are provided in any one of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residues shown in any one of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, while still encoding a protein that maintains its NOVX activities and physiological functions, or a functional fragment thereof.

One aspect of the invention pertains to isolated NOVX proteins, and biologically-active portions thereof, or derivatives, fragments, analogs or homologs thereof. Also provided are polypeptide fragments suitable for use as immunogens to raise anti-NOVX antibodies. In one embodiment, native NOVX proteins can be isolated from cells or tissue sources by an appropriate purification scheme using standard protein purification techniques. In another embodiment, NOVX proteins are produced by recombinant DNA techniques. Alternative to recombinant expression, a NOVX protein or polypeptide can be synthesized chemically using standard peptide synthesis techniques.

An "isolated" or "purified" polypeptide or protein or biologically-active portion thereof is substantially free of cellular material or other contaminating proteins from the cell or tissue source from which the NOVX protein is derived, or substantially free from chemical precursors or other chemicals when chemically synthesized. The language "substantially free of cellular material" includes preparations of NOVX proteins in which the protein is separated from cellular components of the cells from which it is isolated or recombinantly-produced. In one embodiment, the language "substantially free of cellular material" includes preparations of NOVX proteins having less than about 30% (by dry weight) of non-NOVX proteins (also referred to herein as a "contaminating protein"), preferably less than about 20% of non-NOVX proteins, more preferably less than about 10%, even more preferably less than about 5%, and most preferably less than 1-2% of non-NOVX proteins. When the NOVX protein or biologically-active portion thereof is recombinantly-produced, it is also preferably substantially free of culture medium, *i.e.*, culture medium represents less than about 20%, preferably less than about 10%, even more preferably less than about 5%, and most preferably less than 1-2% of the volume of the NOVX protein preparation.

The language "substantially free of chemical precursors or other chemicals" includes preparations of NOVX proteins in which the protein is separated from chemical precursors or other chemicals that are involved in the synthesis of the protein. In one embodiment, the language "substantially free of chemical precursors or other chemicals" includes preparations of NOVX proteins having less than about 30% (by dry weight) of chemical precursors or non-NOVX chemicals, preferably less than about 20%, even more preferably less than about 10% still more preferably less than about 5%, and most preferably less than 1-2% chemical precursors or non-NOVX chemicals.

Biologically-active portions of NOVX proteins include peptides comprising amino acid sequences sufficiently homologous to or derived from the amino acid sequences of the NOVX

proteins (e.g., the amino acid sequence of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94) that include fewer amino acids than the full-length NOVX proteins, and exhibit at least one activity of a NOVX protein. Typically, biologically-active portions comprise a domain or motif with at least one activity of the NOVX protein. A biologically-active portion of a NOVX protein can be a polypeptide which is, for example, 10, 25, 50, 100 or more amino acid residues in length.

Moreover, other biologically-active portions, in which other regions of the protein are deleted, can be prepared by recombinant techniques and evaluated for one or more of the functional activities of a native NOVX protein.

In an embodiment, the NOVX protein has an amino acid sequence of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94. In other embodiments, the NOVX protein is substantially homologous to SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, and retains the functional activity of the protein of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, yet differs in amino acid sequence due to natural allelic variation or mutagenesis, as described in detail, below. Accordingly, in another embodiment, the NOVX protein is a protein that comprises an amino acid sequence at least about 80% homologous to the amino acid sequence of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, and retains the functional activity of the NOVX proteins of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94.

#### **Determining Homology Between Two or More Sequences**

To determine the percent homology of two amino acid sequences or of two nucleic acids, the sequences are aligned for optimal comparison purposes (e.g., gaps can be introduced in the sequence of a first amino acid or nucleic acid sequence for optimal alignment with a second amino or nucleic acid sequence). The amino acid residues or nucleotides at corresponding amino acid positions or nucleotide positions are then compared. When a position in the first sequence is occupied by the same amino acid residue or nucleotide as the corresponding position in the second sequence, then the molecules are homologous at that position (*i.e.*, as used herein amino acid or nucleic acid "homology" is equivalent to amino acid or nucleic acid "identity").

The nucleic acid sequence homology may be determined as the degree of identity between two sequences. The homology may be determined using computer programs known in the art, such as GAP software provided in the GCG program package. See, *J Mol Biol* 48: 443-453, 1970. Using GCG GAP software with the following settings for nucleic acid sequence comparison: GAP creation penalty of 5.0 and GAP extension penalty of 0.3, the coding region of the analogous nucleic acid sequences referred to above exhibits a degree of identity preferably of at least 70%, 75%, 80%, 85%, 90%, 95%, 98%, or 99%, with the CDS (encoding) part of the DNA sequence of SEQ ID NO:2n-1, wherein n is an integer between 1 and 71.

The term "sequence identity" refers to the degree to which two polynucleotide or polypeptide sequences are identical on a residue-by-residue basis over a particular region of comparison. The term "percentage of sequence identity" is calculated by comparing two optimally aligned sequences over that region of comparison, determining the number of positions at which

the identical nucleic acid base (e.g., A, T, C, G, U, or I, in the case of nucleic acids) occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the region of comparison (i.e., the window size), and multiplying the result by 100 to yield the percentage of sequence identity. The term "substantial identity" as used  
5 herein denotes a characteristic of a polynucleotide sequence, wherein the polynucleotide comprises a sequence that has at least 80 percent sequence identity, preferably at least 85 percent identity and often 90 to 95 percent sequence identity, more usually at least 99 percent sequence identity as compared to a reference sequence over a comparison region.

### **Chimeric and Fusion Proteins**

10 The invention also provides NOVX chimeric or fusion proteins. As used herein, a NOVX "chimeric protein" or "fusion protein" comprises a NOVX polypeptide operatively-linked to a non-NOVX polypeptide. An "NOVX polypeptide" refers to a polypeptide having an amino acid sequence corresponding to a NOVX protein of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, whereas a "non-NOVX polypeptide" refers to a polypeptide having an amino acid  
15 sequence corresponding to a protein that is not substantially homologous to the NOVX protein, e.g., a protein that is different from the NOVX protein and that is derived from the same or a different organism. Within a NOVX fusion protein the NOVX polypeptide can correspond to all or a portion of a NOVX protein. In one embodiment, a NOVX fusion protein comprises at least one biologically-active portion of a NOVX protein. In another embodiment, a NOVX fusion protein  
20 comprises at least two biologically-active portions of a NOVX protein. In yet another embodiment, a NOVX fusion protein comprises at least three biologically-active portions of a NOVX protein. Within the fusion protein, the term "operatively-linked" is intended to indicate that the NOVX polypeptide and the non-NOVX polypeptide are fused in-frame with one another. The non-NOVX polypeptide can be fused to the N-terminus or C-terminus of the NOVX polypeptide.

25 In one embodiment, the fusion protein is a GST-NOVX fusion protein in which the NOVX sequences are fused to the C-terminus of the GST (glutathione S-transferase) sequences. Such fusion proteins can facilitate the purification of recombinant NOVX polypeptides.

In another embodiment, the fusion protein is a NOVX protein containing a heterologous signal sequence at its N-terminus. In certain host cells (e.g., mammalian host cells), expression  
30 and/or secretion of NOVX can be increased through use of a heterologous signal sequence.

In yet another embodiment, the fusion protein is a NOVX-immunoglobulin fusion protein in which the NOVX sequences are fused to sequences derived from a member of the immunoglobulin protein family. The NOVX-immunoglobulin fusion proteins of the invention can be incorporated into pharmaceutical compositions and administered to a subject to inhibit an  
35 interaction between a NOVX ligand and a NOVX protein on the surface of a cell, to thereby suppress NOVX-mediated signal transduction *in vivo*. The NOVX-immunoglobulin fusion proteins can be used to affect the bioavailability of a NOVX cognate ligand. Inhibition of the NOVX ligand/NOVX interaction may be useful therapeutically for both the treatment of proliferative and differentiative disorders, as well as modulating (e.g. promoting or inhibiting) cell survival.

Moreover, the NOVX-immunoglobulin fusion proteins of the invention can be used as immunogens to produce anti-NOVX antibodies in a subject, to purify NOVX ligands, and in screening assays to identify molecules that inhibit the interaction of NOVX with a NOVX ligand.

A NOVX chimeric or fusion protein of the invention can be produced by standard recombinant DNA techniques. For example, DNA fragments coding for the different polypeptide sequences are ligated together in-frame in accordance with conventional techniques, *e.g.*, by employing blunt-ended or stagger-ended termini for ligation, restriction enzyme digestion to provide for appropriate termini, filling-in of cohesive ends as appropriate, alkaline phosphatase treatment to avoid undesirable joining, and enzymatic ligation. In another embodiment, the fusion gene can be synthesized by conventional techniques including automated DNA synthesizers. Alternatively, PCR amplification of gene fragments can be carried out using anchor primers that give rise to complementary overhangs between two consecutive gene fragments that can subsequently be annealed and reamplified to generate a chimeric gene sequence (*see, e.g.*, Ausubel, *et al.* (eds.) CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, 1992). Moreover, many expression vectors are commercially available that already encode a fusion moiety (*e.g.*, a GST polypeptide). A NOVX-encoding nucleic acid can be cloned into such an expression vector such that the fusion moiety is linked in-frame to the NOVX protein.

#### **NOVX Agonists and Antagonists**

The invention also pertains to variants of the NOVX proteins that function as either NOVX agonists (*i.e.*, mimetics) or as NOVX antagonists. Variants of the NOVX protein can be generated by mutagenesis (*e.g.*, discrete point mutation or truncation of the NOVX protein). An agonist of the NOVX protein can retain substantially the same, or a subset of, the biological activities of the naturally occurring form of the NOVX protein. An antagonist of the NOVX protein can inhibit one or more of the activities of the naturally occurring form of the NOVX protein by, for example, competitively binding to a downstream or upstream member of a cellular signaling cascade which includes the NOVX protein. Thus, specific biological effects can be elicited by treatment with a variant of limited function. In one embodiment, treatment of a subject with a variant having a subset of the biological activities of the naturally occurring form of the protein has fewer side effects in a subject relative to treatment with the naturally occurring form of the NOVX proteins.

Variants of the NOVX proteins that function as either NOVX agonists (*i.e.*, mimetics) or as NOVX antagonists can be identified by screening combinatorial libraries of mutants (*e.g.*, truncation mutants) of the NOVX proteins for NOVX protein agonist or antagonist activity. In one embodiment, a variegated library of NOVX variants is generated by combinatorial mutagenesis at the nucleic acid level and is encoded by a variegated gene library. A variegated library of NOVX variants can be produced by, for example, enzymatically ligating a mixture of synthetic oligonucleotides into gene sequences such that a degenerate set of potential NOVX sequences is expressible as individual polypeptides, or alternatively, as a set of larger fusion proteins (*e.g.*, for phage display) containing the set of NOVX sequences therein. There are a variety of methods which can be used to produce libraries of potential NOVX variants from a degenerate

oligonucleotide sequence. Chemical synthesis of a degenerate gene sequence can be performed in an automatic DNA synthesizer, and the synthetic gene then ligated into an appropriate expression vector. Use of a degenerate set of genes allows for the provision, in one mixture, of all of the sequences encoding the desired set of potential NOVX sequences. Methods for synthesizing degenerate oligonucleotides are well-known within the art. See, e.g., *Tetrahedron* 39: 3,1983; *Annu. Rev. Biochem.* 53: 323,1984; *Science* 198: 1056, 1984; *Nucl. Acids Res.* 11: 477,1983.

### Anti-NOVX Antibodies

Included in the invention are antibodies to NOVX proteins, or fragments of NOVX proteins or a derivative, fragment, analog, homolog or ortholog thereof. The term "antibody" as used herein refers to immunoglobulin molecules and immunologically active portions of immunoglobulin (Ig) molecules, i.e., molecules that contain an antigen binding site that specifically binds (immunoreacts with) an antigen. Such antibodies include, but are not limited to, polyclonal, monoclonal, chimeric, single chain,  $F_{ab}$ ,  $F_{ab'}$  and  $F_{(ab')_2}$  fragments, and an  $F_{ab}$  expression library. Antibodies may be any of the classes IgG, IgM, IgA, IgE and IgD, and include subclasses such as IgG<sub>1</sub>, IgG<sub>2</sub>, and others. The light chain may be a kappa chain or a lambda chain. Reference herein to antibodies includes a reference to all such classes, subclasses and types of antibody species.

An isolated NOVX full length protein or a portion or fragment thereof, can be used as an immunogen to generate antibodies that immunospecifically bind the antigen, using standard techniques for polyclonal and monoclonal antibody preparation. An antigenic peptide fragment comprises at least 6 amino acid residues of the amino acid sequence of the full length protein, such as an amino acid sequence of SEQ ID NO:2n, wherein n is an integer between 1 and 71 or is 94, and encompasses an epitope. The antigenic peptide may comprise at least 10 amino acid residues, or at least 15, at least 20, or at least 30 amino acid residues. Epitopes may encompassed by the antigenic peptide are regions of the protein that are located on its surface; commonly these are hydrophilic regions.

In certain embodiments of the invention, at least one epitope encompassed by the antigenic peptide is a region of NOVX that is located on the surface of the protein, e.g., a hydrophilic region and may be determined by a hydrophobicity analysis of the NOVX protein sequence. As a means for targeting antibody production, hydropathy plots showing regions of hydrophilicity and hydrophobicity may be generated by any method well known in the art (for example see *Proc. Nat. Acad. Sci. USA* 78: 3824-3828,1981; *J. Mol. Biol.* 157: 105-142, 1982).

The term "epitope" includes any protein determinant capable of specific binding to an immunoglobulin or T-cell receptor. Epitopic determinants usually consist of chemically active surface groupings of molecules such as amino acids or sugar side chains and usually have specific three dimensional structural characteristics, as well as specific charge characteristics. A NOVX polypeptide or a fragment thereof comprises at least one antigenic epitope. An anti-NOVX antibody of the present invention is said to specifically bind to antigen NOVX when the equilibrium

binding constant ( $K_D$ ) is  $\leq 1 \mu\text{M}$ , preferably  $\leq 100 \text{ nM}$ , more preferably  $\leq 10 \text{ nM}$ , and most preferably  $\leq 100 \text{ pM}$  to about  $1 \text{ pM}$ , as measured by assays including radioligand binding assays or similar assays known to skilled artisans.

Various procedures known within the art may be used for the production of polyclonal or monoclonal antibodies directed against a protein of the invention, or against derivatives, fragments, analogs homologs or orthologs thereof (see, for example, *Antibodies: A Laboratory Manual*, Harlow E, and Lane D, 1988, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY).

In another embodiment NOVX nucleic acid molecules are used directly for production of antibodies recognizing NOVX polypeptides. Antibodies can be prepared by genetic or DNA-based immunization. It has been shown that intramuscular immunization of mice with a naked DNA plasmid led to expression of reporter proteins in muscle cells (*Science* 247: 1465-1468, 1990) and that this technology could stimulate an immune response (*Nature* 356: 152-154, 1992). The success of genetic immunization in stimulating both cellular and humoral immune responses has been widely reported (reviewed in: *Annu. Rev. Immunol.* 15: 617-648, 1997; *Immunol. Today* 19: 89-97, 1998; *Annu. Rev. Immunol.* 18: 927-974, 2000). Using this technology, antibodies can be generated through immunization with a cDNA sequence encoding the protein in question. Following genetic immunization, the animal's immune system is activated in response to the synthesis of the foreign protein.

The quantity of protein produced in vivo following genetic immunization is within the picogram to nanogram range, which is much lower than the amounts of protein introduced by conventional immunization protocols. Despite these low levels of protein, a very efficient immune response is achieved due to the foreign protein being expressed directly in, or is quickly taken up by antigen-presenting dendritic cells (*J. Leuk. Biol.* 66: 350-356, 1999; *J. Exp. Med.* 186: 1481-1486, 1997; *Nat. Med.* 2: 1122-1128, 1996). A further increase in the effectivity of genetic immunization is due to the inherent immune-enhancing properties of the DNA itself, i.e., the presence of CpG-motifs in the plasmid backbone, which activate both dendritic cells (*J. Immunol.* 161: 3042-3049, 1998) and B-cells (*Nature* 374: 546-549, 1995).

Genetic immunization and production of high affinity monoclonal antibodies has been successful in mice (*Biotechniques* 16: 616-620, 1994; *J. Biotechnol.* 51: 191-194, 1996; *Hybridoma* 17: 569-576, 1998; *J. Virol.* 72: 4541-4545, 1998; *J. Immunol.* 160: 1458-1465, 1998; *J. Biotechnol.* 73: 119-129, 1999). It has been shown that monoclonal antibodies of the mature IgG subclasses can be obtained (*Hybridoma* 17: 569-576, 1998) and single chain libraries can be generated from genetically immunized mice (*Proc. Natl. Acad. Sci. USA* 95: 669-674, 1998). It has also been shown that genetic immunization can generate antibodies in other species such as rabbits (*J. Lipid. Res.* 38: 2627-2632, 1997) and turkeys (*J. Lipid. Res.* 38: 2627-2632, 1999). Genetic immunization has been used for the production of human antibodies recognizing extracellular targets.

## Humanized Antibodies

Anti NOVX antibodies can further comprise humanized or human antibodies.

Humanization can be performed following methods known in the art (Nature, 321:522-525, 1986; Nature, 332:323-327, 1988; Science, 239:1534-1536, 1988; U.S. Patent No. 5,225,539; and Curr. Op. Struct. Biol., 2:593-596, 1992).

## Human Antibodies

Fully human antibodies are antibody molecules in which the entire sequence of both the light chain and the heavy chain, including the CDRs, arise from human genes. Such antibodies are termed "human antibodies", or "fully human antibodies" herein. Human monoclonal antibodies can be prepared by methods known in the art, see Immunol Today 4: 72, 1983; In: MONOCLONAL ANTIBODIES AND CANCER THERAPY, Alan R. Liss, Inc., pp. 77-96, 1985; Proc Natl Acad Sci USA 80: 2026-2030, 1983; In: MONOCLONAL ANTIBODIES AND CANCER THERAPY, Alan R. Liss, Inc., pp. 77-96, 1985; J. Mol. Biol., 227:381, 1991; J. Mol. Biol., 222:581, 1991; U.S. Patent Nos. 5,545,807; 5,545,806; 5,569,825; 5,625,126; 5,633,425; 5,661,016; Bio/Technology 10, 779-783, 1992; Nature 368 856-859, 1994; Nature 368, 812-13, 1994; Nature Biotechnology 14, 845-51, 1996; Nature Biotechnology 14, 826, 1996; and Intern. Rev. Immunol. 13, 65-93, 1995; PCT publication WO94/02602; WO 96/33735 and WO 96/34096; U.S. Patent Nos. 5,939,598 and 5,916,771; PCT publication WO 99/53049.

## F<sub>ab</sub> Fragments and Single Chain Antibodies

According to the invention, techniques can be adapted for the production of single-chain antibodies specific to an antigenic protein of the invention (see e.g., U.S. Patent No. 4,946,778). In addition, methods can be adapted for the construction of F<sub>ab</sub> expression libraries (see e.g., Science 246: 1275-1281, 1989) to allow rapid and effective identification of monoclonal F<sub>ab</sub> fragments with the desired specificity for a protein or derivatives, fragments, analogs or homologs thereof. Antibody fragments that contain the idiotypes to a protein antigen may be produced by techniques known in the art including, but not limited to: (i) an F<sub>(ab')<sub>2</sub></sub> fragment produced by pepsin digestion of an antibody molecule; (ii) an F<sub>ab</sub> fragment generated by reducing the disulfide bridges of an F<sub>(ab')<sub>2</sub></sub> fragment; (iii) an F<sub>ab</sub> fragment generated by the treatment of the antibody molecule with papain and a reducing agent and (iv) F<sub>v</sub> fragments.

## Bispecific Antibodies

Bispecific antibodies are monoclonal, preferably human or humanized, antibodies that have binding specificities for at least two different antigens. In the present case, one of the binding specificities is for an antigenic protein of the invention. The second binding target is any other antigen, and advantageously is a cell-surface protein or receptor or receptor subunit.

Methods for making bispecific antibodies are known in the art, see Nature, 305:537-539, 1983 and may be purified by affinity chromatography steps, also see WO 93/08829; EMBO J., 10:3655-3659, 1991. For further details of generating bispecific antibodies see, for example,

Methods in Enzymology, 121:210 (1986); WO 96/27011; Science 229:81 (1985); J. Exp. Med. 175:217-225 (1992) J. Immunol. 148(5):1547-1553 (1992); "diabody" technology described in Proc. Natl. Acad. Sci. USA 90:6444-6448 (1993); and single-chain Fv (sFv) dimers in J. Immunol. 152:5368 (1994). Antibodies with more than two valencies are contemplated, see for example J. Immunol. 147:60 (1991).

### **Heteroconjugate Antibodies**

Heteroconjugate antibodies composed of two covalently joined antibodies are also within the scope of the present invention, see for example, U.S. Patent No. 4,676,980; WO 91/00360; WO 92/200373; EP 03089. It is contemplated that the antibodies can be prepared in vitro using known methods in synthetic protein chemistry, including those involving crosslinking agents. For example, immunotoxins can be constructed using a disulfide exchange reaction or by forming a thioether bond. Examples of suitable reagents for this purpose include iminothiolate and methyl-4-mercaptobutyrimidate and those disclosed, for example, in U.S. Patent No. 4,676,980.

### **Effector Function Engineering**

It can be desirable to modify the antibody of the invention with respect to effector function, see for example, J. Exp Med., 176: 1191-1195, 1992; J. Immunol., 148: 2918-2922, 1992; Cancer Research, 53: 2560-2565, 1993; Anti-Cancer Drug Design, 3: 219-230, 1989.

### **Immunoconjugates**

The invention also pertains to immunoconjugates comprising an antibody conjugated to a cytotoxic agent such as a chemotherapeutic agent, toxin (e.g., an enzymatically active toxin of bacterial, fungal, plant, or animal origin, or fragments thereof), or a radioactive isotope (i.e., a radioconjugate).

Chemotherapeutic agents useful in the generation of such immunoconjugates have been described above. Enzymatically active toxins and fragments thereof that can be used include diphtheria A chain, nonbinding active fragments of diphtheria toxin, exotoxin A chain (from *Pseudomonas aeruginosa*), ricin A chain, abrin A chain, modeccin A chain, alpha-sarcin, Aleurites fordii proteins, dianthin proteins, *Phytolacca americana* proteins (PAPI, PAPII, and PAP-S), momordica charantia inhibitor, curcin, crotin, *sapaonaria officinalis* inhibitor, gelonin, mitogellin, restrictocin, phenomycin, enomycin, and the tricothecenes. A variety of radionuclides are available for the production of radioconjugated antibodies. Examples include  $^{212}\text{Bi}$ ,  $^{131}\text{I}$ ,  $^{131}\text{In}$ ,  $^{90}\text{Y}$ , and  $^{186}\text{Re}$ .

Conjugates of the antibody and cytotoxic agent are made using a variety of bifunctional protein-coupling agents such as N-succinimidyl-3-(2-pyridyldithiol) propionate (SPDP), iminothiolane (IT), bifunctional derivatives of imidoesters (such as dimethyl adipimidate HCL), active esters (such as disuccinimidyl suberate), aldehydes (such as glutaraldehyde), bis-azido compounds (such as bis (p-azidobenzoyl) hexanediamine), bis-diazonium derivatives (such as bis-(p-diazoniumbenzoyl)-ethylenediamine), diisocyanates (such as tolyene 2,6-diisocyanate), and bis-active fluorine compounds (such as 1,5-difluoro-2,4-dinitrobenzene). For example, a ricin

immunotoxin can be prepared as described Science, 238: 1098, 1987. Carbon-14-labeled 1-isothiocyanatobenzyl-3-methyldiethylene triaminepentaacetic acid (MX-DTPA) is an exemplary chelating agent for conjugation of radionucleotide to the antibody. See WO94/11026.

5 In another embodiment, the antibody can be conjugated to a "receptor" (such streptavidin) for utilization in tumor pretargeting wherein the antibody-receptor conjugate is administered to the patient, followed by removal of unbound conjugate from the circulation using a clearing agent and then administration of a "ligand" (e.g., avidin) that is in turn conjugated to a cytotoxic agent.

### **Immunoliposomes**

10 The antibodies disclosed herein can also be formulated as immunoliposomes prepared by methods known in the art, such as described in PNAS USA, 82: 3688, 1985; PNAS USA, 77: 4030, 1980; and U.S. Pat. Nos. 4,485,045; 4,544,545; and 5,013,556; J. Biol. Chem., 257: 286-288, 1982; J. National Cancer Inst., 81(19): 1484, 1989.

### **Diagnostic Applications of Antibodies Directed Against the Proteins of the Invention**

15 In one embodiment, methods for the screening of antibodies that possess the desired specificity include, but are not limited to, enzyme linked immunosorbent assay (ELISA) and other immunologically mediated techniques known within the art. In a specific embodiment, selection of antibodies that are specific to a particular domain of an NOVX protein is facilitated by generation of hybridomas that bind to the fragment of an NOVX protein possessing such a domain. Thus, antibodies that are specific for a desired domain within an NOVX protein, or derivatives, fragments, 20 analogs or homologs thereof, are also provided herein.

Antibodies directed against a NOVX protein of the invention may be used in methods known within the art relating to the localization and/or quantitation of a NOVX protein (e.g., for use in measuring levels of the NOVX protein within appropriate physiological samples, for use in diagnostic methods, for use in imaging the protein, and the like). In a given embodiment, 25 antibodies specific to a NOVX protein, or derivative, fragment, analog or homolog thereof, that contain the antibody derived antigen binding domain, are utilized as pharmacologically active compounds (referred to hereinafter as "Therapeutics").

An antibody specific for a NOVX protein of the invention (e.g., a monoclonal antibody or a polyclonal antibody) can be used to isolate a NOVX polypeptide by standard techniques, such as 30 immunoaffinity, chromatography or immunoprecipitation. An antibody to a NOVX polypeptide can facilitate the purification of a natural NOVX antigen from cells, or of a recombinantly produced NOVX antigen expressed in host cells. Moreover, such an anti-NOVX antibody can be used to detect the antigenic NOVX protein (e.g., in a cellular lysate or cell supernatant) in order to evaluate the abundance and pattern of expression of the antigenic NOVX protein. Antibodies directed 35 against a NOVX protein can be used diagnostically to monitor protein levels in tissue as part of a clinical testing procedure, e.g., to, for example, determine the efficacy of a given treatment regimen. Detection can be facilitated by coupling (i.e., physically linking) the antibody to a

detectable substance. Examples of detectable substances include various enzymes, prosthetic groups, fluorescent materials, luminescent materials, bioluminescent materials, and radioactive materials. Examples of suitable enzymes include horseradish peroxidase, alkaline phosphatase,  $\alpha$ -galactosidase, or acetylcholinesterase; examples of suitable prosthetic group complexes include streptavidin/biotin and avidin/biotin; examples of suitable fluorescent materials include umbelliferone, fluorescein, fluorescein isothiocyanate, rhodamine, dichlorotriazinylamine fluorescein, dansyl chloride or phycoerythrin; an example of a luminescent material includes luminol; examples of bioluminescent materials include luciferase, luciferin, and aequorin, and examples of suitable radioactive material include  $^{125}\text{I}$ ,  $^{131}\text{I}$ ,  $^{35}\text{S}$  or  $^3\text{H}$ .

## **Antibody Therapeutics**

Antibodies of the invention, including polyclonal, monoclonal, humanized and fully human antibodies, may be used as therapeutic agents. Such agents will generally be employed to treat or prevent a disease or pathology in a subject. An antibody preparation, preferably one having high specificity and high affinity for its target antigen, is administered to the subject and will generally have an effect due to its binding with the target. Such an effect may be one of two kinds, depending on the specific nature of the interaction between the given antibody molecule and the target antigen in question. In the first instance, administration of the antibody may abrogate or inhibit the binding of the target with an endogenous ligand to which it naturally binds. In this case, the antibody binds to the target and masks a binding site of the naturally occurring ligand, wherein the ligand serves as an effector molecule. Thus the receptor mediates a signal transduction pathway for which ligand is responsible.

Alternatively, the effect may be one in which the antibody elicits a physiological result by virtue of binding to an effector binding site on the target molecule. In this case the target, a receptor having an endogenous ligand which may be absent or defective in the disease or pathology, binds the antibody as a surrogate effector ligand, initiating a receptor-based signal transduction event by the receptor.

A therapeutically effective amount of an antibody of the invention relates generally to the amount needed to achieve a therapeutic objective. As noted above, this may be a binding interaction between the antibody and its target antigen that, in certain cases, interferes with the functioning of the target, and in other cases, promotes a physiological response. The amount required to be administered will furthermore depend on the binding affinity of the antibody for its specific antigen, and will also depend on the rate at which an administered antibody is depleted from the free volume of the subject to which it is administered. Common ranges for therapeutically effective dosing of an antibody or antibody fragment of the invention may be, by way of nonlimiting example, from about 0.1 mg/kg body weight to about 50 mg/kg body weight. Common dosing frequencies may range, for example, from twice daily to once a week.

## Pharmaceutical Compositions of Antibodies

Antibodies specifically binding a protein of the invention, as well as other molecules identified by the screening assays disclosed herein, can be administered for the treatment of various disorders in the form of pharmaceutical compositions. Principles and considerations  
5 involved in preparing such compositions, as well as guidance in the choice of components are provided, for example, in Remington: The Science And Practice Of Pharmacy 19th ed. (Alfonso R. Gennaro, et al., editors) Mack Pub. Co., Easton, Pa. : 1995; Drug Absorption Enhancement : Concepts, Possibilities, Limitations, And Trends, Harwood Academic Publishers, Langhorne, Pa., 1994; and Peptide And Protein Drug Delivery (Advances In Parenteral Sciences, Vol. 4), 1991, M.  
10 Dekker, New York.

If the antigenic protein is intracellular and whole antibodies are used as inhibitors, internalizing antibodies are preferred. However, liposomes can also be used to deliver the antibody, or an antibody fragment, into cells. Where antibody fragments are used, the smallest inhibitory fragment that specifically binds to the binding domain of the target protein is preferred.  
15 For example, based upon the variable-region sequences of an antibody, peptide molecules can be designed that retain the ability to bind the target protein sequence. Such peptides can be synthesized chemically and/or produced by recombinant DNA technology. See, e.g., PNAS USA, 90: 7889-7893, 1993. The formulation herein can also contain more than one active compound as necessary for the particular indication being treated, preferably those with complementary  
20 activities that do not adversely affect each other. Alternatively, or in addition, the composition can comprise an agent that enhances its function, such as, for example, a cytotoxic agent, cytokine, chemotherapeutic agent, or growth-inhibitory agent. Such molecules are suitably present in combination in amounts that are effective for the purpose intended.

The active ingredients can also be entrapped in microcapsules prepared, for example, by  
25 coacervation techniques or by interfacial polymerization, for example, hydroxymethylcellulose or gelatin-microcapsules and poly-(methylmethacrylate) microcapsules, respectively, in colloidal drug delivery systems (for example, liposomes, albumin microspheres, microemulsions, nano-particles, and nanocapsules) or in macroemulsions.

The formulations to be used for in vivo administration must be sterile. This is readily  
30 accomplished by filtration through sterile filtration membranes.

Sustained-release preparations can be prepared. Suitable examples of sustained-release preparations include semipermeable matrices of solid hydrophobic polymers containing the antibody, which matrices are in the form of shaped articles, e.g., films, or microcapsules. Examples of sustained-release matrices include polyesters, hydrogels (for example, poly  
35 (2-hydroxyethyl-methacrylate), or poly(vinylalcohol)), polylactides (U.S. Pat. No. 3,773,919), copolymers of L-glutamic acid and  $\gamma$  ethyl-L-glutamate, non-degradable ethylene-vinyl acetate, degradable lactic acid-glycolic acid copolymers such as the LUPRON DEPOT<sup>TM</sup> (injectable microspheres composed of lactic acid-glycolic acid copolymer and leuprolide acetate), and poly-D-(-)-3-hydroxybutyric acid. While polymers such as ethylene-vinyl acetate and lactic

acid-glycolic acid enable release of molecules for over 100 days, certain hydrogels release proteins for shorter time periods.

### **ELISA Assay**

An agent for detecting an analyte protein is for example, an antibody capable of binding to an analyte protein, preferably an antibody with a detectable label. Antibodies can be polyclonal, or more preferably, monoclonal. An intact antibody, or a fragment thereof (*e.g.*,  $F_{ab}$  or  $F_{(ab)2}$ ) can be used. The term "labeled", with regard to the probe or antibody, is intended to encompass direct labeling of the probe or antibody by coupling (*i.e.*, physically linking) a detectable substance to the probe or antibody, as well as indirect labeling of the probe or antibody by reactivity with another reagent that is directly labeled. Examples of indirect labeling include detection of a primary antibody using a fluorescently-labeled secondary antibody and end-labeling of a DNA probe with biotin such that it can be detected with fluorescently-labeled streptavidin. The term "biological sample" is intended to include tissues, cells and biological fluids isolated from a subject, as well as tissues, cells and fluids present within a subject. Included within the usage of the term "biological sample", therefore, is blood and a fraction or component of blood including blood serum, blood plasma, or lymph. That is, the detection method of the invention can be used to detect an analyte mRNA, protein, or genomic DNA in a biological sample *in vitro* as well as *in vivo*. For example, *in vitro* techniques for detection of an analyte mRNA include Northern hybridizations and *in situ* hybridizations. *In vitro* techniques for detection of an analyte protein include enzyme linked immunosorbent assays (ELISAs), Western blots, immunoprecipitations, and immunofluorescence. *In vitro* techniques for detection of an analyte genomic DNA include Southern hybridizations. Procedures for conducting immunoassays are described, for example in "ELISA: Theory and Practice: Methods in Molecular Biology", Vol. 42, J. R. Crowther (Ed.) Human Press, Totowa, NJ, 1995; "Immunoassay", E. Diamandis and T. Christopoulos, Academic Press, Inc., San Diego, CA, 1996; and "Practice and Theory of Enzyme Immunoassays", P. Tijssen, Elsevier Science Publishers, Amsterdam, 1985. Furthermore, *in vivo* techniques for detection of an analyte protein include introducing into a subject a labeled anti-analyte protein antibody. For example, the antibody can be labeled with a radioactive marker whose presence and location in a subject can be detected by standard imaging techniques.

### **NOVX Recombinant Expression Vectors and Host Cells**

Another aspect of the invention pertains to vectors, preferably expression vectors, containing a nucleic acid encoding a NOVX protein, or derivatives, fragments, analogs or homologs thereof. As used herein, the term "vector" refers to a nucleic acid molecule capable of transporting another nucleic acid to which it has been linked. One type of vector is a "plasmid", which refers to a circular double stranded DNA loop into which additional DNA segments can be ligated. Another type of vector is a viral vector, wherein additional DNA segments can be ligated into the viral genome. Certain vectors are capable of autonomous replication in a host cell into which they are introduced (*e.g.*, bacterial vectors having a bacterial origin of replication and

episomal mammalian vectors). Other vectors (e.g., non-episomal mammalian vectors) are integrated into the genome of a host cell upon introduction into the host cell, and thereby are replicated along with the host genome. Moreover, certain vectors are capable of directing the expression of genes to which they are operatively-linked. Such vectors are referred to herein as "expression vectors". In general, expression vectors of utility in recombinant DNA techniques are often in the form of plasmids. In the present specification, "plasmid" and "vector" can be used interchangeably as the plasmid is the most commonly used form of vector. However, the invention is intended to include such other forms of expression vectors, such as viral vectors (e.g., replication defective retroviruses, adenoviruses and adeno-associated viruses), which serve equivalent functions.

The recombinant expression vectors of the invention comprise a nucleic acid of the invention in a form suitable for expression of the nucleic acid in a host cell, which means that the recombinant expression vectors include one or more regulatory sequences, selected on the basis of the host cells to be used for expression, that is operatively-linked to the nucleic acid sequence to be expressed. Within a recombinant expression vector, "operably-linked" is intended to mean that the nucleotide sequence of interest is linked to the regulatory sequence(s) in a manner that allows for expression of the nucleotide sequence (e.g., in an *in vitro* transcription/translation system or in a host cell when the vector is introduced into the host cell).

The term "regulatory sequence" is intended to include promoters, enhancers and other expression control elements (e.g., polyadenylation signals). Such regulatory sequences are described, for example, in Goeddel, GENE EXPRESSION TECHNOLOGY: METHODS IN ENZYMOLOGY 185, Academic Press, San Diego, Calif. (1990). Regulatory sequences include those that direct constitutive expression of a nucleotide sequence in many types of host cell and those that direct expression of the nucleotide sequence only in certain host cells (e.g., tissue-specific regulatory sequences). It will be appreciated by those skilled in the art that the design of the expression vector can depend on such factors as the choice of the host cell to be transformed, the level of expression of protein desired, etc. The expression vectors of the invention can be introduced into host cells to thereby produce proteins or peptides, including fusion proteins or peptides, encoded by nucleic acids as described herein (e.g., NOVX proteins, mutant forms of NOVX proteins, fusion proteins, etc.).

The recombinant expression vectors of the invention can be designed for expression of NOVX proteins in prokaryotic or eukaryotic cells. For example, NOVX proteins can be expressed in bacterial cells such as *Escherichia coli*, insect cells (using baculovirus expression vectors) yeast cells or mammalian cells. Suitable host cells are discussed further in Goeddel, GENE EXPRESSION TECHNOLOGY: METHODS IN ENZYMOLOGY 185, Academic Press, San Diego, Calif. (1990). Alternatively, the recombinant expression vector can be transcribed and translated *in vitro*, for example using T7 promoter regulatory sequences and T7 polymerase.

Expression of proteins in prokaryotes is most often carried out in *Escherichia coli* with vectors containing constitutive or inducible promoters directing the expression of either fusion or non-fusion proteins. Fusion vectors add a number of amino acids to a protein encoded therein,

usually to the amino terminus of the recombinant protein. Such fusion vectors typically serve three purposes: (i) to increase expression of recombinant protein; (ii) to increase the solubility of the recombinant protein; and (iii) to aid in the purification of the recombinant protein by acting as a ligand in affinity purification. Often, in fusion expression vectors, a proteolytic cleavage site is introduced at the junction of the fusion moiety and the recombinant protein to enable separation of the recombinant protein from the fusion moiety subsequent to purification of the fusion protein. Such enzymes, and their cognate recognition sequences, include Factor Xa, thrombin and enterokinase. Typical fusion expression vectors include pGEX (Pharmacia Biotech Inc; *Gene* 67: 31-40, 1988, pMAL (New England Biolabs, Beverly, Mass.) and pRIT5 (Pharmacia, Piscataway, N.J.) that fuse glutathione S-transferase (GST), maltose E binding protein, or protein A, respectively, to the target recombinant protein.

Examples of suitable inducible non-fusion *E. coli* expression vectors include pTrc ( *Gene* 69:301-315, 1988) and pET 11d (GENE EXPRESSION TECHNOLOGY: METHODS IN ENZYMOLOGY 185, Academic Press, San Diego, Calif. (1990) 60-89).

One strategy to maximize recombinant protein expression in *E. coli* is to express the protein in a host bacteria with an impaired capacity to proteolytically cleave the recombinant protein. See, e.g., GENE EXPRESSION TECHNOLOGY: METHODS IN ENZYMOLOGY 185, Academic Press, San Diego, Calif. (1990) 119-128. Another strategy is to alter the nucleic acid sequence of the nucleic acid to be inserted into an expression vector so that the individual codons for each amino acid are those preferentially utilized in *E. coli* (e.g., *Nucl. Acids Res.* 20: 2111-2118, 1992). Such alteration of nucleic acid sequences of the invention can be carried out by standard DNA synthesis techniques.

In another embodiment, the NOVX expression vector is a yeast expression vector. Examples of vectors for expression in yeast *Saccharomyces cerevisiae* include pYepSec1 (*EMBO J.* 6: 229-234, 1987), pMFa (*Cell* 30: 933-943, 1982), pJRY88 (*Gene* 54: 113-123, 1987), pYES2 (Invitrogen Corporation, San Diego, Calif.), and picZ (Invitrogen Corp, San Diego, Calif.).

Alternatively, NOVX can be expressed in insect cells using baculovirus expression vectors. Baculovirus vectors available for expression of proteins in cultured insect cells (e.g., SF9 cells) include the pAc series (*Mol. Cell. Biol.* 3: 2156-2165, 1983) and the pVL series (*Virology* 170: 31-39, 1989).

In yet another embodiment, a nucleic acid of the invention is expressed in mammalian cells using a mammalian expression vector. Examples of mammalian expression vectors include pCDM8 (*Nature* 329: 840, 1987) and pMT2PC (*EMBO J.* 6: 187-195, 1987). When used in mammalian cells, the expression vector's control functions are often provided by viral regulatory elements. For example, commonly used promoters are derived from polyoma, adenovirus 2, cytomegalovirus, and simian virus 40. For other suitable expression systems for both prokaryotic and eukaryotic cells see, e.g., Chapters 16 and 17 of Sambrook, *et al.*, MOLECULAR CLONING: A LABORATORY MANUAL. 2nd ed., Cold Spring Harbor Laboratory, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y., 1989.

In another embodiment, the recombinant mammalian expression vector is capable of directing expression of the nucleic acid preferentially in a particular cell type (e.g., tissue-specific regulatory elements are used to express the nucleic acid). Tissue-specific regulatory elements are known in the art. Non-limiting examples of suitable tissue-specific promoters include the albumin promoter (liver-specific; *Genes Dev.* 1: 268-277, 1987.), lymphoid-specific promoters (*Adv. Immunol.* 43: 235-275, 1988), in particular promoters of T cell receptors (*EMBO J.* 8: 729-733, 1989) and immunoglobulins (*Cell* 33: 729-740, 1983; *Cell* 33: 741-748, 1983), neuron-specific promoters (e.g., the neurofilament promoter; *PNAS USA* 86: 5473-5477, 1989), pancreas-specific promoters (*Science* 230: 912-916, 1985), and mammary gland-specific promoters (e.g., milk whey promoter; U.S. Pat. No. 4,873,316 and European Application Publication No. 264,166). Developmentally-regulated promoters are also encompassed, e.g., the murine hox promoters (*Science* 249: 374-379, 1990) and the  $\alpha$ -fetoprotein promoter (*Genes Dev.* 3: 537-546, 1989).

The invention further provides a recombinant expression vector comprising a DNA molecule of the invention cloned into the expression vector in an antisense orientation. That is, the DNA molecule is operatively-linked to a regulatory sequence in a manner that allows for expression (by transcription of the DNA molecule) of an RNA molecule that is antisense to NOVX mRNA. Regulatory sequences operatively linked to a nucleic acid cloned in the antisense orientation can be chosen that direct the continuous expression of the antisense RNA molecule in a variety of cell types, for instance viral promoters and/or enhancers, or regulatory sequences can be chosen that direct constitutive, tissue specific or cell type specific expression of antisense RNA. The antisense expression vector can be in the form of a recombinant plasmid, phagemid or attenuated virus in which antisense nucleic acids are produced under the control of a high efficiency regulatory region, the activity of which can be determined by the cell type into which the vector is introduced. For a discussion of the regulation of gene expression using antisense genes see, e.g., "Antisense RNA as a molecular tool for genetic analysis," *Reviews-Trends in Genetics*, Vol. 1(1) 1986.

Another aspect of the invention pertains to host cells into which a recombinant expression vector of the invention has been introduced. The terms "host cell" and "recombinant host cell" are used interchangeably herein. It is understood that such terms refer not only to the particular subject cell but also to the progeny or potential progeny of such a cell. Because certain modifications may occur in succeeding generations due to either mutation or environmental influences, such progeny may not, in fact, be identical to the parent cell, but are still included within the scope of the term as used herein.

A host cell can be any prokaryotic or eukaryotic cell. For example, NOVX protein can be expressed in bacterial cells such as *E. coli*, insect cells, yeast or mammalian cells (such as Chinese hamster ovary cells (CHO) or COS cells). Other suitable host cells are known to those skilled in the art.

Vector DNA can be introduced into prokaryotic or eukaryotic cells via conventional transformation or transfection techniques. As used herein, the terms "transformation" and "transfection" are intended to refer to a variety of art-recognized techniques for introducing foreign

nucleic acid (e.g., DNA) into a host cell, including calcium phosphate or calcium chloride co-precipitation, DEAE-dextran-mediated transfection, lipofection, or electroporation. Suitable methods for transforming or transfecting host cells can be found in Sambrook, *et al.* (MOLECULAR CLONING: A LABORATORY MANUAL. 2nd ed., Cold Spring Harbor Laboratory, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y., 1989), and other laboratory manuals.

For stable transfection of mammalian cells, it is known that, depending upon the expression vector and transfection technique used, only a small fraction of cells may integrate the foreign DNA into their genome. In order to identify and select these integrants, a gene that encodes a selectable marker (e.g., resistance to antibiotics) is generally introduced into the host cells along with the gene of interest. Various selectable markers include those that confer resistance to drugs, such as G418, hygromycin and methotrexate. Nucleic acid encoding a selectable marker can be introduced into a host cell on the same vector as that encoding NOVX or can be introduced on a separate vector. Cells stably transfected with the introduced nucleic acid can be identified by drug selection (e.g., cells that have incorporated the selectable marker gene will survive, while the other cells die).

A host cell of the invention, such as a prokaryotic or eukaryotic host cell in culture, can be used to produce (*i.e.*, express) NOVX protein. Accordingly, the invention further provides methods for producing NOVX protein using the host cells of the invention. In one embodiment, the method comprises culturing the host cell of invention (into which a recombinant expression vector encoding NOVX protein has been introduced) in a suitable medium such that NOVX protein is produced. In another embodiment, the method further comprises isolating NOVX protein from the medium or the host cell.

### **Transgenic NOVX Animals**

The host cells of the invention can also be used to produce non-human transgenic animals by methods known in the art, for example as described in U.S. Patent Nos. 4,736,866; 4,870,009; and 4,873,191; and Hogan, 1986. In: MANIPULATING THE MOUSE EMBRYO, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y.; *Cell* 51: 503 (1987); *Cell* 69: 915, 1992; In: TERATOCARCINOMAS AND EMBRYONIC STEM CELLS: A PRACTICAL APPROACH, Robertson, ed. IRL, Oxford, pp. 113-152, 1987; *Curr. Opin. Biotechnol.* 2: 823-829, 1991; PCT International Publication Nos.: WO 90/11354; WO 91/01140; WO 92/0968; and WO 93/04169; the cre/loxP recombinase system PNAS USA 89: 6232-6236, 1992; a recombinase system *Science* 251:1351-1355, 1991; and clones of the non-human transgenic animals described in *Nature* 385: 810-813, 1997.

### **Pharmaceutical Compositions**

The NOVX nucleic acid molecules, NOVX proteins, and anti-NOVX antibodies (also referred to herein as "active compounds") of the invention, and derivatives, fragments, analogs and homologs thereof, can be incorporated into pharmaceutical compositions suitable for administration. Such compositions typically comprise the nucleic acid molecule, protein, or antibody and a pharmaceutically acceptable carrier. As used herein, "pharmaceutically acceptable

carrier" is intended to include any and all solvents, dispersion media, coatings, antibacterial and antifungal agents, isotonic and absorption delaying agents, and the like, compatible with pharmaceutical administration. Suitable carriers are described in the most recent edition of Remington's Pharmaceutical Sciences, a standard reference text in the field, which is incorporated herein by reference. Preferred examples of such carriers or diluents include, but are not limited to, water, saline, finger's solutions, dextrose solution, and 5% human serum albumin. Liposomes and non-aqueous vehicles such as fixed oils may also be used. The use of such media and agents for pharmaceutically active substances is well known in the art. Except insofar as any conventional media or agent is incompatible with the active compound, use thereof in the compositions is contemplated. Supplementary active compounds can also be incorporated into the compositions.

A pharmaceutical composition of the invention is formulated to be compatible with its intended route of administration. Examples of routes of administration include parenteral, *e.g.*, intravenous, intradermal, subcutaneous, oral (*e.g.*, inhalation), transdermal (*i.e.*, topical), transmucosal, and rectal administration. Solutions or suspensions used for parenteral, intradermal, or subcutaneous application can include the following components: a sterile diluent such as water for injection, saline solution, fixed oils, polyethylene glycols, glycerine, propylene glycol or other synthetic solvents; antibacterial agents such as benzyl alcohol or methyl parabens; antioxidants such as ascorbic acid or sodium bisulfite; chelating agents such as ethylenediaminetetraacetic acid (EDTA); buffers such as acetates, citrates or phosphates, and agents for the adjustment of tonicity such as sodium chloride or dextrose. The pH can be adjusted with acids or bases, such as hydrochloric acid or sodium hydroxide. The parenteral preparation can be enclosed in ampoules, disposable syringes or multiple dose vials made of glass or plastic.

Pharmaceutical compositions suitable for injectable use include sterile aqueous solutions (where water soluble) or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersion. For intravenous administration, suitable carriers include physiological saline, bacteriostatic water, Cremophor EL™ (BASF, Parsippany, N.J.) or phosphate buffered saline (PBS). In all cases, the composition must be sterile and should be fluid to the extent that easy syringeability exists. It must be stable under the conditions of manufacture and storage and must be preserved against the contaminating action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (for example, glycerol, propylene glycol, and liquid polyethylene glycol, and the like), and suitable mixtures thereof. The proper fluidity can be maintained, for example, by the use of a coating such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. Prevention of the action of microorganisms can be achieved by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, ascorbic acid, thimerosal, and the like. In many cases, it will be preferable to include isotonic agents, for example, sugars, polyalcohols such as manitol, sorbitol, sodium chloride in the composition. Prolonged absorption of the injectable compositions can be brought about by including in the composition an agent which delays absorption, for example, aluminum monostearate and gelatin.

Sterile injectable solutions can be prepared by incorporating the active compound (e.g., a NOVX protein or anti-NOVX antibody) in the required amount in an appropriate solvent with one or a combination of ingredients enumerated above, as required, followed by filtered sterilization. Generally, dispersions are prepared by incorporating the active compound into a sterile vehicle  
5 that contains a basic dispersion medium and the required other ingredients from those enumerated above. In the case of sterile powders for the preparation of sterile injectable solutions, methods of preparation are vacuum drying and freeze-drying that yields a powder of the active ingredient plus any additional desired ingredient from a previously sterile-filtered solution thereof.

Oral compositions generally include an inert diluent or an edible carrier. They can be  
10 enclosed in gelatin capsules or compressed into tablets. For the purpose of oral therapeutic administration, the active compound can be incorporated with excipients and used in the form of tablets, troches, or capsules. Oral compositions can also be prepared using a fluid carrier for use as a mouthwash, wherein the compound in the fluid carrier is applied orally and swished and expectorated or swallowed. Pharmaceutically compatible binding agents, and/or adjuvant  
15 materials can be included as part of the composition. The tablets, pills, capsules, troches and the like can contain any of the following ingredients, or compounds of a similar nature: a binder such as microcrystalline cellulose, gum tragacanth or gelatin; an excipient such as starch or lactose, a disintegrating agent such as alginic acid, Primogel, or corn starch; a lubricant such as magnesium stearate or Sterotes; a glidant such as colloidal silicon dioxide; a sweetening agent such as  
20 sucrose or saccharin; or a flavoring agent such as peppermint, methyl salicylate, or orange flavoring.

For administration by inhalation, the compounds are delivered in the form of an aerosol spray from pressured container or dispenser which contains a suitable propellant, e.g., a gas such as carbon dioxide, or a nebulizer.

25 Systemic administration can also be by transmucosal or transdermal means. For transmucosal or transdermal administration, penetrants appropriate to the barrier to be permeated are used in the formulation. Such penetrants are generally known in the art, and include, for example, for transmucosal administration, detergents, bile salts, and fusidic acid derivatives. Transmucosal administration can be accomplished through the use of nasal sprays or  
30 suppositories. For transdermal administration, the active compounds are formulated into ointments, salves, gels, or creams as generally known in the art.

The compounds can also be prepared in the form of suppositories (e.g., with conventional suppository bases such as cocoa butter and other glycerides) or retention enemas for rectal delivery.

35 In one embodiment, the active compounds are prepared with carriers that will protect the compound against rapid elimination from the body, such as a controlled release formulation, including implants and microencapsulated delivery systems. Biodegradable, biocompatible polymers can be used, such as ethylene vinyl acetate, polyanhydrides, polyglycolic acid, collagen, polyorthoesters, and polylactic acid. Methods for preparation of such formulations will be apparent  
40 to those skilled in the art. The materials can also be obtained commercially from Alza Corporation

and Nova Pharmaceuticals, Inc. Liposomal suspensions (including liposomes targeted to infected cells with monoclonal antibodies to viral antigens) can also be used as pharmaceutically acceptable carriers. These can be prepared according to methods known to those skilled in the art, for example, as described in U.S. Patent No. 4,522,811.

5 It is especially advantageous to formulate oral or parenteral compositions in dosage unit form for ease of administration and uniformity of dosage. Dosage unit form as used herein refers to physically discrete units suited as unitary dosages for the subject to be treated; each unit containing a predetermined quantity of active compound calculated to produce the desired therapeutic effect in association with the required pharmaceutical carrier. The specification for the dosage unit forms of the invention are dictated by and directly dependent on the unique characteristics of the active compound and the particular therapeutic effect to be achieved, and the limitations inherent in the art of compounding such an active compound for the treatment of individuals.

10 The nucleic acid molecules of the invention can be inserted into vectors and used as gene therapy vectors. Gene therapy vectors can be delivered to a subject by, for example, intravenous injection, local administration (*see, e.g.*, U.S. Patent No. 5,328,470) or by stereotactic injection (*see, e.g.*, PNAS. USA 91: 3054-3057, 1994). The pharmaceutical preparation of the gene therapy vector can include the gene therapy vector in an acceptable diluent, or can comprise a slow release matrix in which the gene delivery vehicle is imbedded. Alternatively, where the complete gene delivery vector can be produced intact from recombinant cells, *e.g.*, retroviral vectors, the pharmaceutical preparation can include one or more cells that produce the gene delivery system.

The pharmaceutical compositions can be included in a container, pack, or dispenser together with instructions for administration.

## 25 **Screening and Detection Methods**

The isolated nucleic acid molecules of the invention can be used to express NOVX protein (*e.g.*, via a recombinant expression vector in a host cell in gene therapy applications), to detect NOVX mRNA (*e.g.*, in a biological sample) or a genetic lesion in a NOVX gene, and to modulate NOVX activity, as described further, below. In addition, the NOVX proteins can be used to screen drugs or compounds that modulate the NOVX protein activity or expression as well as to treat disorders characterized by insufficient or excessive production of NOVX protein or production of NOVX protein forms that have decreased or aberrant activity compared to NOVX wild-type protein (*e.g.*; diabetes (regulates insulin release); obesity (binds and transport lipids); metabolic disturbances associated with obesity, the metabolic syndrome X as well as anorexia and wasting disorders associated with chronic diseases and various cancers, and infectious disease (possesses anti-microbial activity) and the various dyslipidemias. In addition, the anti-NOVX antibodies of the invention can be used to detect and isolate NOVX proteins and modulate NOVX activity. In yet a further aspect, the invention can be used in methods to influence appetite, absorption of nutrients and the disposition of metabolic substrates in both a positive and negative fashion.

The invention further pertains to novel agents identified by the screening assays described herein and uses thereof for treatments as described, *supra*.

### Screening Assays

5 The invention provides a method (also referred to herein as a "screening assay") for identifying modulators, *i.e.*, candidate or test compounds or agents (*e.g.*, peptides, peptidomimetics, small molecules or other drugs) that bind to NOVX proteins or have a stimulatory or inhibitory effect on, *e.g.*, NOVX protein expression or NOVX protein activity. The invention also includes compounds identified in the screening assays described herein.

10 In one embodiment, the invention provides assays for screening candidate or test compounds which bind to or modulate the activity of the membrane-bound form of a NOVX protein or polypeptide or biologically-active portion thereof. The test compounds of the invention can be obtained using any of the numerous approaches in combinatorial library methods known in the art, including: biological libraries; spatially addressable parallel solid phase or solution phase libraries; synthetic library methods requiring deconvolution; the "one-bead one-compound" library method; 15 and synthetic library methods using affinity chromatography selection. The biological library approach is limited to peptide libraries, while the other four approaches are applicable to peptide, non-peptide oligomer or small molecule libraries of compounds. See, *e.g.*, *Anticancer Drug Design* 12: 145, 1997.

A "small molecule" as used herein, is meant to refer to a composition that has a molecular 20 weight of less than about 5 kD and most preferably less than about 4 kD. Small molecules can be, *e.g.*, nucleic acids, peptides, polypeptides, peptidomimetics, carbohydrates, lipids or other organic or inorganic molecules. Libraries of chemical and/or biological mixtures, such as fungal, bacterial, or algal extracts, are known in the art and can be screened with any of the assays of the invention.

25 Examples of methods for the synthesis of molecular libraries can be found in the art, for example in: PNAS U.S.A. 90: 6909, 1993; PNAS U.S.A. 91: 11422, 1994; *J. Med. Chem.* 37: 2678, 1994; *Science* 261: 1303, 1993; *Angew. Chem. Int. Ed. Engl.* 33: 2059, 1994; *Angew. Chem. Int. Ed. Engl.* 33: 2061, 1994; and *J. Med. Chem.* 37: 1233, 1994.

30 Libraries of compounds may be presented in solution (*e.g.*, *Biotechniques* 13: 412-421, 1992), or on beads (*Nature* 354: 82-84, 1991), on chips (*Nature* 364: 555-556, 1993), bacteria (U.S. Patent No. 5,223,409), spores (U.S. Patent 5,233,409), plasmids (PNAS USA 89: 1865-1869, 1992) or on phage (*Science* 249: 386-390, 1990; *Science* 249: 404-406, 1990; PNAS USA 87: 6378-6382, 1990; *J. Mol. Biol.* 222: 301-310, 1991; U.S. Patent No. 5,233,409.).

35 In one embodiment, an assay is a cell-based assay in which a cell which expresses a membrane-bound form of NOVX protein, or a biologically-active portion thereof, on the cell surface is contacted with a test compound and the ability of the test compound to bind to a NOVX protein determined. The ability of the test compound to bind to the NOVX protein can be detected for example, by coupling the test compound with a radioisotope (*e.g.*  $^{125}\text{I}$ ,  $^{35}\text{S}$ ,  $^{14}\text{C}$ , or  $^3\text{H}$ , either directly or indirectly), or enzymatic label (*e.g.* horseradish peroxidase, alkaline phosphatase, or luciferase) such that binding of the test compound to the NOVX protein or biologically-active portion thereof

can be determined by detecting the labeled compound in a complex. In one embodiment, the assay comprises contacting a cell which expresses a NOVX protein, or a biologically-active portion thereof, with a known compound which binds NOVX to form an assay mixture, contacting the assay mixture with a test compound, and determining the ability of the test compound to interact  
5 with a NOVX protein, either compared to or in competition with the known compound.

In another embodiment, an assay is a cell-based comprising contacting a cell expressing a NOVX protein, or a biologically-active portion thereof, with a test compound and determining the ability of the test compound to modulate (e.g., stimulate or inhibit) the activity of the NOVX protein or biologically-active portion thereof. As used herein, a "target molecule" is a molecule with which  
10 a NOVX protein binds or interacts. In one embodiment, a NOVX target molecule is a component of a signal transduction pathway that facilitates transduction of an extracellular signal

Determining the ability of the NOVX protein to bind to or interact with a NOVX target molecule can be accomplished for example, by one of the methods described above or by determining the activity of the target molecule. For example, the activity of the target molecule can  
15 be determined by detecting induction of a cellular second messenger of the target (*i.e.* intracellular  $\text{Ca}^{2+}$ , diacylglycerol,  $\text{IP}_3$ , *etc.*), detecting catalytic/enzymatic activity of the target an appropriate substrate, detecting the induction of a reporter gene (comprising a NOVX-responsive regulatory element operatively linked to a nucleic acid encoding a detectable marker, *e.g.*, luciferase), or detecting a cellular response, for example, cell survival, cellular differentiation, or cell proliferation.

In yet another embodiment, an assay of the invention is a cell-free assay comprising contacting a NOVX protein or biologically-active portion thereof with a test compound and determining directly or indirectly the ability of the test compound to bind to the NOVX protein or biologically-active portion thereof.  
20

In still another embodiment, an assay is a cell-free assay comprising contacting NOVX  
25 protein or biologically-active portion thereof with a test compound and determining the ability of the test compound to modulate (e.g. stimulate or inhibit) the activity of the NOVX protein or biologically-active portion thereof.

The cell-free assays of the invention are amenable to use of both the soluble form or the membrane-bound form of NOVX protein. In the case of cell-free assays comprising the  
30 membrane-bound form of NOVX protein, it may be desirable to utilize a solubilizing agent such that the membrane-bound form of NOVX protein is maintained in solution. Examples of such solubilizing agents include non-ionic detergents such as n-octylglucoside, n-dodecylglucoside, n-dodecylmaltoside, octanoyl-N-methylglucamide, decanoyl-N-methylglucamide, Triton<sup>®</sup> X-100, Triton<sup>®</sup> X-114, Thesit<sup>®</sup>, Isotridecypoly(ethylene glycol ether)<sub>n</sub>,  
35 N-dodecyl--N,N-dimethyl-3-ammonio-1-propane sulfonate, 3-(3-cholamidopropyl) dimethylamminiol-1-propane sulfonate (CHAPS), or 3-(3-cholamidopropyl)dimethylamminiol-2-hydroxy-1-propane sulfonate (CHAPSO).

In more than one embodiment of the above assay methods of the invention, it may be desirable to immobilize either NOVX protein or its target molecule to facilitate separation of  
40 complexed from uncomplexed forms of one or both of the proteins, as well as to accommodate

automation of the assay. In one embodiment, a fusion protein can be provided that adds a domain that allows one or both of the proteins to be bound to a matrix. For example, GST-NOVX fusion proteins or GST-target fusion proteins can be adsorbed onto glutathione sepharose beads (Sigma Chemical, St. Louis, MO) or glutathione derivatized microtiter plates. The NOVX protein or its target molecule can be immobilized utilizing conjugation of biotin and streptavidin using techniques well-known within the art (e.g., biotinylation kit, Pierce Chemicals, Rockford, Ill.). Alternatively, antibodies reactive with NOVX protein or target molecules, but which do not interfere with binding of the NOVX protein to its target molecule, can be derivatized to the wells of the plate. Methods for detecting such complexes, in addition to those described above for the GST-immobilized complexes, include immunodetection of complexes using antibodies reactive with the NOVX protein or target molecule, as well as enzyme-linked assays that rely on detecting an enzymatic activity associated with the NOVX protein or target molecule.

In another embodiment, modulators of NOVX protein expression are identified in a method wherein a cell is contacted with a candidate compound and the expression of NOVX mRNA or protein in the cell is determined. The level of expression of NOVX mRNA or protein in the presence of the candidate compound is compared to the level of expression of NOVX mRNA or protein in the absence of the candidate compound. The candidate compound can then be identified as a modulator of NOVX mRNA or protein expression based upon this comparison. For example, when expression of NOVX mRNA or protein is greater (*i.e.*, statistically significantly greater) in the presence of the candidate compound than in its absence, the candidate compound is identified as a stimulator of NOVX mRNA or protein expression. Alternatively, when expression of NOVX mRNA or protein is less (statistically significantly less) in the presence of the candidate compound than in its absence, the candidate compound is identified as an inhibitor of NOVX mRNA or protein expression. The level of NOVX mRNA or protein expression in the cells can be determined by methods described herein for detecting NOVX mRNA or protein.

In yet another aspect of the invention, the NOVX proteins can be used as "bait proteins" in a two-hybrid assay or three hybrid assay (see, e.g., U.S. Patent No. 5,283,317; *Cell* 72: 223-232, 1993; *J. Biol. Chem.* 268: 12046-12054, 1993; *Biotechniques* 14: 920-924, 1993; *Oncogene* 8: 1693-1696, 1993; and WO 94/10300), to identify other proteins that bind to or interact with NOVX ("NOVX-binding proteins" or "NOVX-bp") and modulate NOVX activity. Such NOVX-binding proteins are also involved in the propagation of signals by the NOVX proteins as, for example, upstream or downstream elements of the NOVX pathway.

The invention further pertains to novel agents identified by the aforementioned screening assays and uses thereof for treatments as described herein.

## **Detection Assays**

Portions or fragments of the cDNA sequences identified herein (and the corresponding complete gene sequences) can be used in numerous ways as polynucleotide reagents. By way of example, and not of limitation, these sequences can be used to: (i) map their respective genes on a chromosome; and, thus, locate gene regions associated with genetic disease; (ii) identify an

individual from a minute biological sample (tissue typing); and (iii) aid in forensic identification of a biological sample. Some of these applications are described in the subsections, below.

### Chromosome Mapping

Once the sequence (or a portion of the sequence) of a gene has been isolated, this sequence can be used to map the location of the gene on a chromosome ("chromosome mapping"). Briefly, NOVX genes can be mapped to chromosomes by preparing PCR primers (preferably 15-25 bp in length) from the NOVX sequences. Computer analysis of the NOVX sequences can be used to rapidly select primers that do not span more than one exon in the genomic DNA, thus complicating the amplification process. These primers can then be used for PCR screening of somatic cell hybrids containing individual human chromosomes. Only those hybrids containing the human gene corresponding to the NOVX sequences will yield an amplified fragment. See for example *Science* 220: 919-924 (1983). Somatic cell hybrids containing only fragments of human chromosomes can also be produced by using human chromosomes with translocations and deletions.

Fluorescence *in situ* hybridization (FISH) of a DNA sequence to a metaphase chromosomal spread can further be used to provide a precise chromosomal location, see, Verma, *et al.*, HUMAN CHROMOSOMES: A MANUAL OF BASIC TECHNIQUES (Pergamon Press, New York 1988).

Once a sequence has been mapped to a precise chromosomal location, the physical position of the sequence on the chromosome can be correlated with genetic map data, *e.g.*, in McKusick, MENDELIAN INHERITANCE IN MAN, available on-line through Johns Hopkins University Welch Medical Library). The relationship between genes and disease, mapped to the same chromosomal region, can then be identified through linkage analysis (co-inheritance of physically adjacent genes), described in, *e.g.*, Egeland, *et al.*, 1987. *Nature*, 325: 783-787.

Moreover, differences in the DNA sequences between individuals affected and unaffected with a disease associated with the NOVX gene, can be determined. If a mutation is observed in some or all of the affected individuals but not in any unaffected individuals, then the mutation is likely to be the causative agent of the particular disease. Comparison of affected and unaffected individuals generally involves first looking for structural alterations in the chromosomes, such as deletions or translocations that are visible from chromosome spreads or detectable using PCR based on that DNA sequence. Ultimately, complete sequencing of genes from several individuals can be performed to confirm the presence of a mutation and to distinguish mutations from polymorphisms.

### Predictive Medicine

The invention also pertains to the field of predictive medicine in which diagnostic assays, prognostic assays, pharmacogenomics, and monitoring clinical trials are used for prognostic (predictive) purposes to thereby treat an individual prophylactically. Accordingly, one aspect of the invention relates to diagnostic assays for determining NOVX protein and/or nucleic acid expression as well as NOVX activity, in the context of a biological sample (*e.g.*, blood, serum, cells, tissue) to

thereby determine whether an individual is afflicted with a disease or disorder, or is at risk of developing a disorder, associated with aberrant NOVX expression or activity. The disorders include, but are not limited to metabolic disorders, diabetes, obesity, infectious disease, anorexia, cancer-associated cachexia, cancer, neurodegenerative disorders, Alzheimer's Disease,

5 Parkinson's Disorder, immune disorders, and hematopoietic disorders, and the various dyslipidemias, metabolic disturbances associated with obesity, the metabolic syndrome X and wasting disorders associated with chronic diseases and various cancers.

Another aspect of the invention provides methods for determining NOVX protein, nucleic acid expression or activity in an individual to thereby select appropriate therapeutic or prophylactic agents for that individual (referred to herein as "pharmacogenomics"). Pharmacogenomics allows for the selection of agents (e.g., drugs) for therapeutic or prophylactic treatment of an individual based on the genotype of the individual (e.g., the genotype of the individual examined to determine the ability of the individual to respond to a particular agent.)

Yet another aspect of the invention pertains to monitoring the influence of agents (e.g., drugs, compounds) on the expression or activity of NOVX in clinical trials.

An exemplary method for detecting the presence or absence of NOVX in a biological sample involves obtaining a biological sample from a test subject and contacting the biological sample with a compound or an agent capable of detecting NOVX protein or the nucleic acid (e.g., mRNA, genomic DNA) that encodes NOVX protein such that the presence of NOVX is detected in the biological sample. An agent for detecting NOVX mRNA or genomic DNA is a labeled nucleic acid probe capable of hybridizing to NOVX mRNA or genomic DNA as described herein. An agent for detecting NOVX protein can be an antibody capable of binding to NOVX protein, preferably an antibody with a detectable label as described herein. In one embodiment, the biological sample contains protein molecules from the test subject. Alternatively, the biological sample can contain mRNA molecules from the test subject or genomic DNA molecules from the test subject.

The invention also encompasses kits for detecting the presence of NOVX in a biological sample. For example, the kit can comprise: a labeled compound or agent capable of detecting NOVX protein or mRNA in a biological sample; means for determining the amount of NOVX in the sample; and/or means for comparing the amount of NOVX in the sample with a standard. The compound or agent can be packaged in a suitable container. The kit can further comprise instructions for using the kit to detect NOVX protein or nucleic acid.

Assays described herein can be used to determine whether a subject can be administered an agent (e.g., an agonist, antagonist, peptidomimetic, protein, peptide, nucleic acid, small molecule, or other drug candidate) to treat a disease or disorder associated with aberrant NOVX expression or activity.

The methods of the invention can also be used to detect genetic lesions in a NOVX gene (characterized by at least one of an alteration affecting the integrity of a gene encoding a NOVX-protein, or the misexpression of the NOVX gene), thereby determining if a subject with the lesioned gene is at risk for a disorder characterized by aberrant cell proliferation and/or differentiation. For example, such genetic lesions can be detected by ascertaining the existence of

at least one of: (i) a deletion of one or more nucleotides from a NOVX gene; (ii) an addition of one or more nucleotides to a NOVX gene; (iii) a substitution of one or more nucleotides of a NOVX gene, (iv) a chromosomal rearrangement of a NOVX gene; (v) an alteration in the level of a messenger RNA transcript of a NOVX gene, (vi) aberrant modification of a NOVX gene, such as of the methylation pattern of the genomic DNA, (vii) the presence of a non-wild-type splicing pattern of a messenger RNA transcript of a NOVX gene, (viii) a non-wild-type level of a NOVX protein, (ix) allelic loss of a NOVX gene, and (x) inappropriate post-translational modification of a NOVX protein.

In certain embodiments, detection of the lesion involves the use of a probe/primer in a polymerase chain reaction (PCR) (see, e.g., U.S. Patent Nos. 4,683,195 and 4,683,202), such as anchor PCR or RACE PCR, or, alternatively, in a ligation chain reaction (LCR) (see, e.g., *Science* 241: 1077-1080, 1988; and *PNAS USA* 91: 360-364, 1994), the latter of which can be particularly useful for detecting point mutations in the NOVX-gene (see, *Nucl. Acids Res.* 23: 675-682, 1995). This method can include the steps of collecting a sample of cells from a patient, isolating nucleic acid (e.g., genomic, mRNA or both) from the cells of the sample, contacting the nucleic acid sample with one or more primers that specifically hybridize to a NOVX gene under conditions such that hybridization and amplification of the NOVX gene (if present) occurs, and detecting the presence or absence of an amplification product, or detecting the size of the amplification product and comparing the length to a control sample

Alternative amplification methods include: self sustained sequence replication (*PNAS USA* 87: 1874-1878, 1990), transcriptional amplification system (*PNAS USA* 86: 1173-1177, 1989); Q $\beta$  Replicase (*BioTechnology* 6: 1197, 1988), or any other nucleic acid amplification method, followed by the detection of the amplified molecules using techniques well known to those of skill in the art. These detection schemes are especially useful for the detection of nucleic acid molecules if such molecules are present in very low numbers.

In an alternative embodiment, mutations in a NOVX gene from a sample cell can be identified by alterations in restriction enzyme cleavage patterns. For example, sample and control DNA is isolated, amplified (optionally), digested with one or more restriction endonucleases, and fragment length sizes are determined by gel electrophoresis and compared. Differences in fragment length sizes between sample and control DNA indicates mutations in the sample DNA. Moreover, the use of sequence specific ribozymes (see, e.g., U.S. Patent No. 5,493,531) can be used to score for the presence of specific mutations by development or loss of a ribozyme cleavage site.

In other embodiments, genetic mutations in NOVX can be identified by hybridizing a sample and control nucleic acids, e.g., DNA or RNA, to high-density arrays containing hundreds or thousands of oligonucleotides probes (e.g., *Human Mutation* 7: 244-255, 1996.; *Nat. Med.* 2: 753-759, 1996). For example, by two dimensional arrays containing light-generated DNA probes. Briefly, a first hybridization array of probes can be used to scan through long stretches of DNA in a sample and control to identify base changes between the sequences by making linear arrays of sequential overlapping probes. This step allows the identification of point mutations. This is

followed by a second hybridization array that allows the characterization of specific mutations by using smaller, specialized probe arrays complementary to all variants or mutations detected. Each mutation array is composed of parallel probe sets, one complementary to the wild-type gene and the other complementary to the mutant gene.

5 In yet another embodiment, any of a variety of sequencing reactions known in the art can be used to directly sequence the NOVX gene and detect mutations by comparing the sequence of the sample NOVX with the corresponding wild-type (control) sequence. For examples of sequencing reactions see *PNAS USA* 74: 560 (1977); *PNAS USA* 74: 5463 (1977); *Biotechniques* 19: 448, 1995; WO 94/16101; *Adv. Chromatography* 36: 127-162, 1996; and *Appl. Biochem. Biotechnol.* 38: 147-159, 1993.

Other methods for detecting mutations in the NOVX gene include methods in which protection from cleavage agents is used to detect mismatched bases in RNA/RNA or RNA/DNA heteroduplexes see, e.g., *Science* 230: 1242, 1985; *PNAS USA* 85: 4397, 1988; *Methods Enzymol.* 217: 286-295, 1992.

15 In still another embodiment, the mismatch cleavage reaction employs one or more proteins that recognize mismatched base pairs in double-stranded DNA (so called "DNA mismatch repair" enzymes) in defined systems for detecting and mapping point mutations in NOVX cDNAs, see *Carcinogenesis* 15: 1657-1662, 1994; U.S. Patent No. 5,459,039.

20 In other embodiments, alterations in electrophoretic mobility will be used to identify mutations in NOVX genes. For example, single strand conformation polymorphism (SSCP) may be used to detect differences in electrophoretic mobility between mutant and wild type nucleic acids, (*PNAS USA*: 86: 2766, 1989; *Mutat. Res.* 285: 125-144, 1993; *Genet. Anal. Tech. Appl.* 9: 73-79, 1992; *Trends Genet.* 7: 5, 1991).

25 In yet another embodiment, the movement of mutant or wild-type fragments in polyacrylamide gels containing a gradient of denaturant is assayed using denaturing gradient gel electrophoresis (DGGE) e.g. *Nature* 313: 495, 1985; *Biophys. Chem.* 265: 12753, 1987. Examples of other techniques for detecting point mutations include, but are not limited to, selective oligonucleotide hybridization, selective amplification, or selective primer extension, e.g. *Nature* 324: 163, 1986; *PNAS USA* 86: 6230, 1989.

30 Alternatively, allele specific amplification technology that depends on selective PCR amplification may be used in conjunction with the instant invention. Oligonucleotides used as primers for specific amplification may carry the mutation of interest in the center of the molecule (so that amplification depends on differential hybridization e.g., *Nucl. Acids Res.* 17: 2437-2448, 1989) or at the extreme 3'-terminus of one primer where, under appropriate conditions, mismatch  
35 can prevent, or reduce polymerase extension (e.g., *Tibtech.* 11: 238, 1993). In addition it may be desirable to introduce a novel restriction site in the region of the mutation to create cleavage-based detection, e.g., *Mol. Cell Probes* 6: 1, 1992. It is anticipated that in certain embodiments amplification may also be performed using *Taq* ligase for amplification, e.g., *PNAS. USA* 88: 189, 1991. In such cases, ligation will occur only if there is a perfect match at the 3'-terminus of the 5'

sequence, making it possible to detect the presence of a known mutation at a specific site by looking for the presence or absence of amplification.

The methods described herein may be performed, for example, by utilizing pre-packaged diagnostic kits comprising at least one probe nucleic acid or antibody reagent described herein, which may be conveniently used, e.g., in clinical settings to diagnose patients exhibiting symptoms or family history of a disease or illness involving a NOVX gene.

### **Pharmacogenomics**

Agents, or modulators that have a stimulatory or inhibitory effect on NOVX activity (e.g., NOVX gene expression), as identified by a screening assay described herein can be administered to individuals to treat (prophylactically or therapeutically) disorders. The disorders include but are not limited to, e.g., those diseases, disorders and conditions listed above, and more particularly include those diseases, disorders, or conditions associated with homologs of a NOVX protein, such as those summarized in Table A.

Pharmacogenomics, the study of the relationship between an individual's genotype and that individual's response to a foreign compound or drug permits the selection of effective agents (e.g., drugs) for prophylactic or therapeutic treatments based on a consideration of the individual's genotype. Such pharmacogenomics can further be used to determine appropriate dosages and therapeutic regimens. Accordingly, the activity of NOVX protein, expression of NOVX nucleic acid, or mutation content of NOVX genes in an individual can be determined to thereby select appropriate agent(s) for therapeutic or prophylactic treatment of the individual.

Pharmacogenomics deals with clinically significant hereditary variations in the response to drugs due to altered drug disposition and abnormal action in affected persons, e.g., *Clin. Exp. Pharmacol. Physiol.*, 23: 983-985, 1996; *Clin. Chem.*, 43: 254-266, 1997. In general, two types of pharmacogenetic conditions can be differentiated. Genetic conditions transmitted as a single factor altering the way drugs act on the body (altered drug action) or genetic conditions transmitted as single factors altering the way the body acts on drugs (altered drug metabolism).

Thus, the activity of NOVX protein, expression of NOVX nucleic acid, or mutation content of NOVX genes in an individual can be determined to thereby select appropriate agent(s) for therapeutic or prophylactic treatment of the individual. In addition, pharmacogenetic studies can be used to apply genotyping of polymorphic alleles encoding drug-metabolizing enzymes to the identification of an individual's drug responsiveness phenotype. This knowledge, when applied to dosing or drug selection, can avoid adverse reactions or therapeutic failure and thus enhance therapeutic or prophylactic efficiency when treating a subject with a NOVX modulator, such as a modulator identified by one of the exemplary screening assays described herein.

### **Monitoring of Effects During Clinical Trials**

Monitoring the influence of agents (e.g., drugs, compounds) on the expression or activity of NOVX (e.g., the ability to modulate aberrant cell proliferation and/or differentiation) can be applied not only in basic drug screening, but also in clinical trials. For example, the effectiveness

of an agent determined by a screening assay as described herein can be monitored in clinical trials utilizing the same or similar assay. In such clinical trials, the expression or activity of NOVX and, preferably, other genes that have been implicated in, for example, a cellular proliferation or immune disorder can be used as a "read out" or markers of the immune responsiveness of a particular cell.

By way of example, and not of limitation, genes, including NOVX, that are modulated in cells by treatment with an agent (e.g., compound, drug or small molecule, e.g., identified in a screening assay as described herein) can be identified and/or quantified by Northern blot analysis or RT-PCR, as described herein, or alternatively by measuring the amount of protein produced, by one of the methods as described herein, or by measuring the levels of activity of NOVX or other genes. In this manner, the gene expression pattern can serve as a marker, indicative of the physiological response of the cells to the agent.

In one embodiment, the invention provides a method for monitoring the effectiveness of treatment of a subject with an agent (e.g., an agonist, antagonist, protein, peptide, peptidomimetic, nucleic acid, small molecule, or other drug candidate identified by the screening assays described herein) comprising the steps of (i) obtaining a pre-administration sample from a subject prior to administration of the agent; (ii) detecting the level of expression of a NOVX protein, mRNA, or genomic DNA in the preadministration sample; (iii) obtaining one or more post-administration samples from the subject; (iv) detecting the level of expression or activity of the NOVX protein, mRNA, or genomic DNA in the post-administration samples; (v) comparing the level of expression or activity of the NOVX protein, mRNA, or genomic DNA in the pre-administration sample with the NOVX protein, mRNA, or genomic DNA in the post administration sample or samples; and (vi) altering the administration of the agent to the subject accordingly.

### **Methods of Treatment**

The invention provides for both prophylactic and therapeutic methods of treating a subject at risk of (or susceptible to) a disorder or having a disorder associated with aberrant NOVX expression or activity.

### **Diseases and Disorders**

Diseases and disorders that are characterized by increased (relative to a subject not suffering from the disease or disorder) levels or biological activity may be treated with Therapeutics that antagonize (i.e., reduce or inhibit) activity. Therapeutics that antagonize activity may be administered in a therapeutic or prophylactic manner. Therapeutics that may be utilized include, but are not limited to: (i) an aforementioned peptide, or analogs, derivatives, fragments or homologs thereof; (ii) antibodies to an aforementioned peptide; (iii) nucleic acids encoding an aforementioned peptide; (iv) administration of antisense nucleic acid and nucleic acids that are "dysfunctional" (i.e., due to a heterologous insertion within the coding sequences of coding sequences to an aforementioned peptide) that are utilized to "knockout" endogenous function of an aforementioned peptide by homologous recombination (e.g., *Science* 244: 1288-1292, 1989); or

(v) modulators (*i.e.*, inhibitors, agonists and antagonists, including additional peptide mimetic of the invention or antibodies specific to a peptide of the invention) that alter the interaction between an aforementioned peptide and its binding partner.

Diseases and disorders that are characterized by decreased (relative to a subject not suffering from the disease or disorder) levels or biological activity may be treated with Therapeutics that increase (*i.e.*, are agonists to) activity. Therapeutics that upregulate activity may be administered in a therapeutic or prophylactic manner. Therapeutics that may be utilized include, but are not limited to, an aforementioned peptide, or analogs, derivatives, fragments or homologs thereof; or an agonist that increases bioavailability.

Increased or decreased levels can be readily detected by quantifying peptide and/or RNA, by obtaining a patient tissue sample (*e.g.*, from biopsy tissue) and assaying it *in vitro* for RNA or peptide levels, structure and/or activity of the expressed peptides (or mRNAs of an aforementioned peptide). Methods that are well-known within the art include, but are not limited to, immunoassays (*e.g.*, by Western blot analysis, immunoprecipitation followed by sodium dodecyl sulfate (SDS) polyacrylamide gel electrophoresis, immunocytochemistry, *etc.*) and/or hybridization assays to detect expression of mRNAs (*e.g.*, Northern assays, dot blots, *in situ* hybridization, and the like).

#### **Prophylactic Methods**

In one aspect, the invention provides a method for preventing, in a subject, a disease or condition associated with an aberrant NOVX expression or activity, by administering to the subject an agent that modulates NOVX expression or at least one NOVX activity. Subjects at risk for a disease that is caused or contributed to by aberrant NOVX expression or activity can be identified by, for example, any or a combination of diagnostic or prognostic assays as described herein. Administration of a prophylactic agent can occur prior to the manifestation of symptoms characteristic of the NOVX aberrancy, such that a disease or disorder is prevented or, alternatively, delayed in its progression. Depending upon the type of NOVX aberrancy, for example, a NOVX agonist or NOVX antagonist agent can be used for treating the subject. The appropriate agent can be determined based on screening assays described herein. The prophylactic methods of the invention are further discussed in the following subsections.

#### **Therapeutic Methods**

Another aspect of the invention pertains to methods of modulating NOVX expression or activity for therapeutic purposes. The modulatory method of the invention involves contacting a cell with an agent that modulates one or more of the activities of NOVX protein activity associated with the cell. An agent that modulates NOVX protein activity can be an agent as described herein, such as a nucleic acid or a protein, a naturally-occurring cognate ligand of a NOVX protein, a peptide, a NOVX peptidomimetic, or other small molecule. In one embodiment, the agent stimulates one or more NOVX protein activity. Examples of such stimulatory agents include active NOVX protein and a nucleic acid molecule encoding NOVX that has been introduced into the cell. In another embodiment, the agent inhibits one or more NOVX protein activity. Examples of such

inhibitory agents include antisense NOVX nucleic acid molecules and anti-NOVX antibodies. These modulatory methods can be performed *in vitro* (e.g., by culturing the cell with the agent) or, alternatively, *in vivo* (e.g., by administering the agent to a subject). As such, the invention provides methods of treating an individual afflicted with a disease or disorder characterized by aberrant expression or activity of a NOVX protein or nucleic acid molecule. In one embodiment, the method involves administering an agent (e.g., an agent identified by a screening assay described herein), or combination of agents that modulates (e.g., up-regulates or down-regulates) NOVX expression or activity. In another embodiment, the method involves administering a NOVX protein or nucleic acid molecule as therapy to compensate for reduced or aberrant NOVX expression or activity.

Stimulation of NOVX activity is desirable *in situations* in which NOVX is abnormally downregulated and/or in which increased NOVX activity is likely to have a beneficial effect. One example of such a situation is where a subject has a disorder characterized by aberrant cell proliferation and/or differentiation (e.g., cancer or immune associated disorders). Another example of such a situation is where the subject has a gestational disease (e.g., preeclampsia).

#### **Determination of the Biological Effect of the Therapeutic**

In various embodiments of the invention, suitable *in vitro* or *in vivo* assays are performed to determine the effect of a specific Therapeutic and whether its administration is indicated for treatment of the affected tissue.

In various specific embodiments, *in vitro* assays may be performed with representative cells of the type(s) involved in the patient's disorder, to determine if a given Therapeutic exerts the desired effect upon the cell type(s). Compounds for use in therapy may be tested in suitable animal model systems including, but not limited to rats, mice, chicken, cows, monkeys, rabbits, and the like, prior to testing in human subjects. Similarly, for *in vivo* testing, any of the animal model system known in the art may be used prior to administration to human subjects.

The invention will be further described in the following examples, which do not limit the scope of the invention described in the claims.

### **EXAMPLES**

#### **Example A: Polynucleotide and Polypeptide Sequences, and Homology Data**

##### **Example 1. NOV1, CG101729: FGFR4 variant**

NOV1 of the present invention are novel proteins which bear sequence similarity to RIBOSOMAL PROTEIN S6 KINASE (RSK) ALPHA 1, nucleic acids that encode these proteins or fragments thereof, and antibodies that bind immunospecifically to these proteins. In one embodiment, a NOV1 gene encodes for a novel splice variant of ribosomal protein S6 kinase alpha 1 with 11 amino acid residues deleted resulting a shorter exon 10. Novel SNP variants are also provided.

The RSK family comprises growth factor-regulated serine/threonine kinases, known also as p90(rsk). Homologs of RSK exist in several species (Nature 384: 567-570, 1996). The highly

conserved feature of all members of the RSK family is the presence of 2 nonidentical kinase catalytic domains. RSKs are implicated in the activation of the mitogen-activated kinase (MAPK) cascade and the stimulation of cell proliferation (at the transition between phases G0 and G1 of the cell cycle) and differentiation. The cloning and characterization of 3 genes encoding 3 isoforms of ribosomal protein S6 kinase (RSK): HU1 (RPS6KA1), HU2 (RPS6KA2), and HU3 (RPS6KA3) has been described (Am. J. Physiol. 266: C351-C359, 1994). The HU1 cDNA (GenBank L07597 ) encodes a predicted 735-amino acid protein containing 2 distinct consensus ATP-binding site sequences. Northern blot and RNase protection analyses detected an approximately 3.5-kb HU1 transcript in lymphocytes, skeletal muscle, liver, and adipose tissue.

The RPS6KA1 gene has been mapped to chromosome 3.

A possible mechanism by which the RAS-MAPK signaling pathway mediates growth factor-dependent cell survival has been proposed (Science 286: 1358-1362, 1999). The MAP-activated kinases, the RSKs, catalyzed the phosphorylation of the proapoptotic protein BAD at ser112 both in vitro and in vivo. The RSK-induced phosphorylation of BAD at ser112 suppressed BAD-mediated apoptosis in neurons. The RSKs are known to phosphorylate the transcription factor CREB at ser133. Activated CREB promoted cell survival, and inhibition of CREB phosphorylation at ser133 triggered apoptosis. It has been suggested that the MAP kinase signaling pathway promotes cell survival by a dual mechanism comprising the posttranslational modification and inactivation of a component of the cell death machinery and the increased transcription of prosurvival genes.

Xenopus laevis egg extracts immunodepleted of RSK have been shown to lose their capacity to undergo mitotic arrest in response to activation of the Mos-MEK1-p42 MAPK cascade of protein kinases. Replenishing RSK-depleted extracts with catalytically competent RSK protein restored the ability of the extracts to undergo mitotic arrest. RSK appears to be essential for cytosstatic factor arrest (Science 286: 1362-1365, 1999). Whether cytosstatic factor arrest is mediated by the protein kinase p90 RSK, which is phosphorylated and activated by MAPK, has been investigated by expressing a constitutively activated form of RSK in Xenopus embryos. Expression resulted in cleavage arrest. RSK appeared to be the mediator of MAPK-dependent cytosstatic factor arrest in vertebrate unfertilized eggs. Since RSK expression did not activate the endogenous MAPK pathway, MAPK required no other substrate for induction of cytosstatic factor arrest. Cytosstatic factor arrest does not appear to be a consequence of direct regulation of the spindle assembly checkpoint or the anaphase-promoting complex by MAPK (Science 286: 1365-1367, 1999).

Mice deficient in S6 kinase-1 have been made (EMBO J. 17: 6649-6659, 1998) and were viable and fertile, but exhibit a conspicuous reduction in body size during embryogenesis, an effect that was mostly overcome by adulthood. Other mice deficient for S6 kinase-1, a known effector of the phosphatidylinositol-3-OH kinase signaling pathway, are hypoinsulinemic and glucose intolerant (Nature 408: 994-997, 2000). Whereas insulin resistance was not observed in isolated muscle, such mice exhibit a sharp reduction in glucose-induced insulin secretion and in pancreatic insulin content. This is not due to a lesion in glucose sensing or insulin production, but

to a reduction in pancreatic endocrine mass, which is accounted for by a selective decrease in beta-cell size. It has been suggested that the observed phenotype closely parallels those of preclinical type II diabetes mellitus, in which malnutrition-induced hypoinsulinemia predisposes individuals to glucose intolerance.

- 5           The NOV1 family of novel nucleic acids and polypeptides clones includes NOV1a through NOV1t, SEQ ID NOs: 1-40, and the nucleotide and encoded polypeptide sequences are shown in Table 1A. In a particular embodiment NOV1 nucleic acid sequence is SEQ ID NO:39, wherein each of residues X<sub>1</sub>, X<sub>2</sub>, X<sub>5</sub>, X<sub>6</sub>, X<sub>8</sub>, X<sub>9</sub>, X<sub>10</sub>, X<sub>14</sub>, X<sub>17</sub> is either C or T; and each of residues X<sub>3</sub>, X<sub>4</sub>, X<sub>7</sub>, X<sub>11</sub>, X<sub>12</sub>, X<sub>13</sub>, X<sub>15</sub>, X<sub>16</sub>, X<sub>18</sub> is either G or A. Nucleic acid sequence SEQ ID NO:39 encodes
- 10           polypeptide SEQ ID NO:40, wherein residue Z<sub>1</sub> is S or F; Z<sub>2</sub> is C or R; Z<sub>3</sub> is A or T; Z<sub>4</sub> is Q or R; Z<sub>5</sub> is L or P; Z<sub>6</sub> is W or R; Z<sub>7</sub> is H or R; Z<sub>8</sub> is S or P; Z<sub>9</sub> is S or P; Z<sub>10</sub> is W or R; Z<sub>11</sub> is A or T; Z<sub>12</sub> is M or V; Z<sub>13</sub> is M or V or A; Z<sub>14</sub> is E or K; Z<sub>15</sub> is M or V; Z<sub>16</sub> is S or P; Z<sub>17</sub> is T or A; B<sub>1</sub> is L or S; B<sub>2</sub> is L or P; B<sub>3</sub> is K or E; B<sub>4</sub> is L or P; B<sub>5</sub> is V or D; and B<sub>6</sub> is L or P. Equivalent nucleic acid and
- 15           polypeptide substitutions apply to other NOV1 sequences as would be appreciated by one of skill in the art, and are encompassed in the present invention.

NUCDISC: discrimination of nuclear localization signals
  pat4: none
  pat7: none
  bipartite: none
  content of basic residues: 10.0%
  NLS Score: -0.47

NNCN: Reinhardt's method for Cytoplasmic/Nuclear discrimination
  Prediction: nuclear
  Reliability: 55.5

COIL: Lupas's algorithm to detect coiled-coil regions
  total: 0 residues
-----
Final Results (k = 9/23):

  55.6 %: extracellular, including cell wall
  22.2 %: nuclear
  11.1 %: vacuolar
  11.1 %: mitochondrial
>> prediction for CG101729-02 is exc (k=9)

```

A search of the NOV1a protein against the Geneseq database, a proprietary database that contains sequences published in patents and patent publication, yielded several homologous proteins shown in Table 1C.

5

<b>Geneseq Identifier</b>	<b>Protein/Organism/Length [Patent #, Date]</b>	<b>NOV1a Residues/ Match Residues</b>	<b>Identities/ Similarities for the Matched Region</b>	<b>Expect Value</b>

TVHUF4	fibroblast growth factor receptor 4 precursor - human, 802 aa.	1..789 1..802	704/802 (87%) 717/802 (88%)	0.0

PFam analysis predicts that the NOV1a protein contains domains as shown in the Table 1E. Specific amino acid residues of NOV1a for each domain is shown in column 2, equivalent domains in the other NOV1 proteins of the invention are also encompassed herein.

Table 1E. Domain Analysis of NOV1a			
Pfam Domain	NOV1a Match Region Amino acid residues:	Identities/ Similarities for the Matched Region	Expect Value
ig	165..226	21/65 (32%) 49/65 (75%)	3.7e-09
ig	264..335	19/75 (25%) 49/75 (65%)	9.7e-06
pkinase	454..727	98/319 (31%) 235/319 (74%)	2.3e-86

### Example 2. NOV2, CG124800, Complement Factor 1 Precursor.

The present invention encompasses NOV2, a novel protein bearing sequence similarity to COMPLEMENT FACTOR I PRECURSOR, nucleic acids that encode this protein or fragments thereof, and antibodies that bind immunospecifically to NOV2.

C3 inactivator, or factor I ('eye'), is a proteolytic enzyme that destroys the hemolytic and immune-adherence activities of cell-bound, activated C3. Patients with 'type I essential hypercatabolism of C3' were homozygous for an inherited deficiency of C3 inactivator and relatives

had values for the inactivator about 50% of normal (Proc. Nat. Acad. Sci. 69: 2910-2913, 1972; J. Immun. 107: 19-27, 1971; Clin. Exp. Immun. 27: 23-29, 1977; Quart. J. Med. 87: 385-401, 1994). Patients had recurrent pyogenic infections, self-limiting vasculitic illness and neisserial infections. Polymorphism of C3b inactivator ("Factor I", Nomenclature Committee of the IUIS, J. Immun. 127: 1261-1262, 1981) has been described (Hum. Genet. 71: 45-48, 1985). A variant, tentatively designated FI<sup>\*</sup>C was described found as a result 305 patient sera (Hum. Genet. 82: 393, 1989). Factor I is composed of 2 disulfide-linked polypeptide chains with molecular weights of 50,000 and 38,000 daltons. It is synthesized as a single-chain precursor which undergoes intracellular proteolytic processing.

- 10 The factor I gene has been mapped to chromosome 4, specifically 4q25 (J. Biol. Chem. 262: 10065-10071, 1987),

The NOV2 clone was analyzed, and the nucleotide and encoded polypeptide sequences are shown in Table 2A.

Table 2A. NOV2 Sequence Analysis

### Example 3. NOV3, CG185793: MMP15

The present invention encompasses NOV3, a novel protein bearing sequence similarity to MATRIX METALLOPROTEINASE-15, nucleic acids that encode this protein or fragments thereof, and antibodies that bind immunospecifically to NOV3.

10

Matrix metalloproteinases (MMPs) are zinc-binding endopeptidases that degrade various components of the extracellular matrix. They have been implicated in normal and pathologic processes including tissue remodeling, wound healing, angiogenesis, and tumor invasion. MMPs have different substrate specificities and are encoded by different genes. MMP15 has been isolated from a human lung cDNA library and has 73.9% sequence similarity to MMP14 (600754), a membrane-localized MMP that also contains a C-terminal transmembrane segment.

15

MMP15-specific antibodies have detected a 72-kD protein in lung cell membranes and demonstrated by Northern blotting that MMP15 is widely expressed as a 3.6-kb transcript, particularly in liver, placenta, testis, colon, and intestine (Europ. J. Biochem. 231: 602-608, 1995).

20

The MMP15 gene has been mapped to chromosome 6q13-q21 by isotopic in situ hybridization

#### Example 4. NOV4, CG186317, ADAM22-like

The present invention encompasses NOV4, a novel protein bearing sequence similarity to ADAM22, nucleic acids that encode this protein or fragments thereof, and antibodies that bind immunospecifically to NOV4.

ADAM (a disintegrin and metalloproteinase) and MDC (metalloproteinase-like, disintegrin-like, and cysteine-rich) proteins, are a class of cell adhesion molecules. NOV 4 XX is a novel splice form of ADAM22 with 17 amino acids (residues 787V to 817E) different from ADAM 22. The ADAM22 gene has been mapped to chromosome 2q33 (Gene 237: 61-70, 1999). The

5 NOV4 clone was analyzed, and the nucleotide and encoded polypeptide sequences are shown in Table 4A.

#### Example 5. NOV5, CG192920

The NOV5 family of novel nucleic acids and polypeptides clones includes NOV5a through NOV5c, SEQ ID NOs: 45-50 and 188, and the nucleotide and encoded polypeptide sequences are shown in Table 5A. In a particular embodiment NOV5 polypeptide is SEQ ID NO:188, wherein residue  $X_1$  is present or absent and when present is RLRKPKITWSLRHSEDGICRISLTCSVED

GGNTVMYTWTP LQKEAVVSQGESH LNVSWRSENHPNL TCTASNPVSRSSHQFLSENICSG  
(corresponding to amino acid residues 319-408 of SEQ ID NO:48);  $X_2$  is residue S or G;  $X_3$  is  
residue E or K;  $X_4$  is present or absent and when present is residue V.

Equivalent nucleic acid and polypeptide substitutions apply to other NOV5 sequences as  
5 would be appreciated by one of skill in the art, and are encompassed in the present invention.

Further analysis of the NOV6b protein yielded the following properties shown in Table 6C.

Table 6C. Protein Sequence Properties NOV6b	
SignalP analysis:	No signal sequence cleavage site detected
PSORT II analysis:	

```

PSG:  a new signal peptide prediction method
      N-region:  length 5;  pos.chg 0;  neg.chg 1
      H-region:  length 11;  peak value  0.00
      PSG score:  -4.40

GvH:  von Heijne's method for signal seq. recognition
      GvH score (threshold: -2.1):  -4.96
      possible cleavage site:  between 18 and 19

>>> Seems to have no N-terminal signal peptide

ALOM: Klein et al's method for TM region allocation
      Init position for calculation: 1
      Tentative number of TMS(s) for the threshold 0.5:  0
      number of TMS(s) .. fixed
      PERIPHERAL Likelihood = 3.13 (at 55)
      ALOM score:  3.13 (number of TMSs: 0)

MITDISC: discrimination of mitochondrial targeting seq

```

A search of the NOV6b protein against the Geneseq database, a proprietary database that contains sequences published in patents and patent publication, yielded several homologous proteins shown in Table 6D.

5

Table 6D. Geneseq Results for NOV6b				
Geneseq Identifier	Protein/Organism/Length [Patent #, Date]	NOV6b Residues/ Match Residues	Identities/ Similarities for the Matched Region	Expect Value

AAE18826	Human FGF-21 protein - Homo sapiens, 209 aa. [US2002001825-A1, 03-JAN-2002]	1..167 25..194	167/167 (100%) 205/205 (100%)	8.9e-91
AAE05078	Human fibroblast growth factor (FGF) homologue, zFGF11 protein - Homo sapiens, 208 aa. [2000US-0477886, 05-JAN-2000]	1..167 1..205	167/167 (100%) 205/205 (100%)	8.9e-91
AAB68417	Amino acid sequence of human fibroblast growth factor-21 (FGF-21) - Homo sapiens, 209 aa. [WO200136640-A2, 25-MAY-2001]	1..167 1..206	167/167 (100%) 206/206 (100%)	8.9e-91
AAG65667	Human fibroblast growth factor (FGF)-21 - Homo sapiens, 209 aa. [WO200172957-A2, 04-OCT-2001]	1..167 26..206	167/167 (100%) 206/206 (100%)	8.9e-91

In a BLAST search of public sequence databases, the NOV6b protein was found to have homology to the proteins shown in the BLASTP data in Table 6E.

Table 6E. Public BLASTP Results for NOV6b				
Protein Accession Number	Protein/Organism/Length	NOV6b Residues/ Match Residues	Identities/ Similarities for the Matched Portion	Expect Value
Q9NSA1	Fibroblast growth factor-21 precursor (FGF-21) - Homo sapiens (Human), 209 aa.	1..167 1..206	167/167 (100%) 206/206 (100%)	9.3e-91
Q8N683	Fibroblast growth factor 21 - Homo sapiens (Human), 209 aa.	1..167 1..206	205/206 (99%) 205/206 (99%)	9.3e-91
CAC51204	Sequence 1 from Patent WO0149849 - Homo sapiens (Human), 208 aa.	1..167 1..205	205/206 (99%) 205/206 (99%)	5.1e-90

5

PFam analysis predicts that the NOV6b protein contains the domains shown in the Table 6F. Specific amino acid residues of NOV6b for each domain is shown in column 2, equivalent domains in the other NOV6 proteins of the invention are also encompassed herein.

Table 6F. Domain Analysis of NOV6b			
Pfam Domain	NOV6b Match Region Amino Acid Residues:	Score	Expect Value
FGF	15..140	27.7	2.8e-08

10

### Example 7. NOV7, CG55051, Alpha-2 Macroglobulin-like

The NOV7 family of novel nucleic acids and polypeptides clones includes NOV7a through NOV7c, SEQ ID Nos: 77-82, and the nucleotide and encoded polypeptide sequences are shown in Table 7A. In a particular embodiment NOV7 nucleic acid sequence is SEQ ID NO:81, wherein residue X<sub>1</sub> is either T or C. Nucleic acid sequence SEQ ID NO:81 encodes polypeptide SEQ ID NO:82, wherein residue Z<sub>1</sub> is I or T. Equivalent nucleic acid and polypeptide substitutions apply to other NOV7 sequences as would be appreciated by one of skill in the art, and are encompassed in the present invention.

A search of the NOV7a protein against the Geneseq database, a proprietary database that contains sequences published in patents and patent publication, yielded several homologous proteins shown in Table 7C.

5

TABLE 7C. GENESEQ RESULTS FOR NOV7a				
Geneseq Identifier	Protein/Organism/Length [Patent #, Date]	NOV7a Residues/ Match Residues	Identities/ Similarities for the Matched Region	Expect Value
AAG63549	A human alpha-2 macroglobulin-like polypeptide - Homo sapiens, 912 aa.	1..596 31..623	595/596 (99%) 595/596 (99%)	0.0
AAG63550	A human alpha-2 macroglobulin-like polypeptide variant - Homo sapiens, 899 aa.	1..596 18..613	595/596 (99%) 595/596 (99%)	0.0
AAG63551	A human alpha-2 macroglobulin-like polypeptide - Homo sapiens, 882 aa.	1..596 1..596	595/596 (99%) 595/596 (99%)	0.0

In a BLAST search of public sequence databases, the NOV7a protein was found to have homology to the proteins shown in the BLASTP data in Table 7D.

Table 7D. Public BLASTP Results for NOV7a				
Protein Accession Number	Protein/Organism/Length	NOV7a Residues/ Match Residues	Identities/ Similarities for the Matched Portion	Expect Value
CAD48670	Sequence 1 from Patent WO0229058 - Homo sapiens (Human), 1492 aa.	1..596 18..617	576/600 (96%) 579/600 (96%)	0.0
P01023	Alpha-2-macroglobulin precursor (Alpha-2-M) - Homo sapiens (Human), 1474 aa	4..596 29..619	207/593 (34%) 324/593 (54%)	0.0
CAA01533	ALPHA 2-MACROGLOBULIN 690-740 - Homo sapiens (Human), 1484 aa	4..596 29..619	207/593 (34%) 324/593 (54%)	0.0

PFam analysis predicts that the NOV7a protein contains the domains shown in the Table 7F. Specific amino acid residues of NOV7a for each domain is shown in column 2, equivalent domains in the other NOV7 proteins of the invention are also encompassed herein.

Table 7F. Domain Analysis of NOV7a			
Pfam Domain	NOV7a Match Region Amino acid residues	Score	Expect Value
A2M_N	1..596	278.3	1e-79

#### Example 8. NOV8, CG55060, Antileukoproteinase 1

The NOV8 family of novel nucleic acids and polypeptides clones includes NOV8a through NOV8g, SEQ ID Nos: 83-96, and the nucleotide and encoded polypeptide sequences are shown in Table 8A. In a particular embodiment NOV8 nucleic acid sequence is SEQ ID NO:95, wherein each of residues  $X_1$ ,  $X_2$ ,  $X_3$ ,  $X_4$ , and  $X_5$ , is either T or C. Nucleic acid sequence SEQ ID NO:95 encodes polypeptide SEQ ID NO:96, wherein each of residues  $Z_1$  is F or S;  $Z_2$  is L or P;  $Z_3$  is C or R;  $Z_4$  is L or S; and  $Z_5$  is C or R. Equivalent nucleic acid and polypeptide substitutions apply to other NOV8 sequences as would be appreciated by one of skill in the art, and are encompassed in the present invention.

A search of the NOV9g protein against the Geneseq database, a proprietary database that contains sequences published in patents and patent publication, yielded several homologous proteins shown in Table 9D.

5

Table 9D. Geneseq Results for NOV9g				
			Identities/	

Identifier	Date]	Residues/ Match Residues	Similarities for the Matched Region	Value
ABG76949	Human protein, homologous to LIV-1, designated NOV1 - Homo sapiens, 755 aa. [WO200255705-A2, 18-JUL-2002]	1..733 1..753	733/733 (99%) 736/738 (99%)	0.0
ABR48228	Human bladder cancer associated protein sequence SEQ ID NO:177 - Homo sapiens, 755 aa. [WO2003003906-A2, 16-JAN-2003]	1..733 1..753	733/733 (99%) 736/738 (99%)	0.0
ABU56608	Lung cancer-associated polypeptide #201 - Unidentified, 755 aa. [WO200286443-A2, 31-OCT-2002]	1..733 1..753	733/733 (99%) 736/738 (99%)	0.0
AAM51198	Human breast cancer 4 gene (BCR4)-encoded protein - Homo sapiens, 755 aa. [WO200216939-A2, 28-FEB-2002]	1..733 1..753	733/733 (99%) 736/738 (99%)	0.0
ABG61889	Prostate cancer-associated protein #90 - Mammalia, 755 aa. [WO200230268-A2, 18-APR-2002]	1..733 1..753	733/733 (99%) 736/738 (99%)	0.0

In a BLAST search of public sequence databases, the NOV9g protein was found to have homology to the proteins shown in the BLASTP data in Table 9E.

Table 9E. Public BLASTP Results for NOV9g				
Protein Accession Number	Protein/Organism/Length	NOV9g Residues/ Match Residues	Identities/ Similarities for the Matched Portion	Expect Value
CAD42374	Sequence 1 from Patent WO0216939 - Homo sapiens (Human), 755 aa.	1..733 1..753	752/753(99%) 753/753 (99%)	0.0
Q13433	Estrogen regulated LIV-1 protein - Homo sapiens (Human), 749 aa.	1..733 19..747	727/735 (98%) 730/736 (98%)	0.0
G02273	LIV-1 protein - human, 752 aa.	1..733 19..747	729/736 (98%) 730/736 (98%)	0.0

5

PFam analysis predicts that the NOV9g protein contains the domains shown in the Table 9F. Specific amino acid residues of NOV9g for each domain is shown in column 2, equivalent domains in the other NOV9 proteins of the invention are also encompassed herein.

Table 9F. Domain Analysis of NOV9g			
Pfam Domain	NOV11g Match Region Amino Acid Residues:	Score	Expect Value
Zip	301-725	443.7	1.6e-129

**Example 10. NOV10, CG59356, NUCLEAR RECEPTOR SUBFAMILY 4**

The NOV10 clone was analyzed, and the nucleotide and encoded polypeptide sequences  
5 are shown in Table 10A.

#### Example B: Sequencing Methodology and Identification of NOVX Clones

1. **GeneCalling™ Technology:** A method of differential gene expression profiling between two or more samples (Nature Biotechnology 17:198-803 1999) was used to identify NOVX genes. Briefly cDNA was derived from various human samples of whole tissue, primary cells or tissue cultured primary cells or cell lines representing multiple tissue types, normal and diseased states, physiological states, and developmental states from different donors. Samples were obtained as. Cells and cell lines may have been treated with biological or chemical agents that regulate gene expression, for example, growth factors, chemokines or steroids. The cDNA thus derived was then digested with up to as many as 120 pairs of restriction enzymes and pairs of linker-adaptors specific for each pair of restriction enzymes were ligated to the appropriate end. The restriction digestion generates a mixture of unique cDNA gene fragments. Limited PCR amplification is performed with primers homologous to the linker adapter sequence where one primer is biotinylated and the other is fluorescently labeled. The doubly labeled material is isolated and the fluorescently labeled single strand is resolved by capillary gel electrophoresis. A computer algorithm compares the electropherograms from an experimental and control group for each of the restriction digestions. This and additional sequence-derived information is used to predict the identity of each differentially expressed gene fragment using a variety of genetic databases. The identity of the gene fragment is confirmed by additional, gene-specific competitive PCR or by isolation and sequencing of the gene fragment.

2. **SeqCalling™ Technology:** The cDNA thus derived was then sequenced using CuraGen's proprietary SeqCalling technology. Sequence traces were evaluated manually and edited for corrections if appropriate. cDNA sequences from all samples were assembled together, sometimes including public human sequences, using bioinformatic programs to produce a

consensus sequence for each assembly. Sequences were included as components for assembly when the extent of identity with another component was at least 95% over 50 bp. Each assembly represents a gene or portion thereof and includes information on variants, such as splice forms single nucleotide polymorphisms (SNPs), insertions, deletions and other sequence variations.

5           **3. PathCalling™ Technology:** The NOVX nucleic acid sequences are derived by laboratory screening of cDNA library by the two-hybrid approach by methods previously described (Nature 403: 623-627, 2000; U. S. Patents 6,057,101 and 6,083,693).

10           **4. RACE:** Techniques based on the polymerase chain reaction such as rapid amplification of cDNA ends (RACE), were used to isolate or complete the predicted sequence of the cDNA of the invention. Usually multiple clones were sequenced from one or more human samples to derive the sequences for fragments. Various human tissue samples from different donors were used for the RACE reaction. The sequences derived from these procedures were included in the SeqCalling Assembly process described in preceding paragraphs.

15           **5. Exon Linking:** The NOVX target sequences identified in the present invention were subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse  
20           primer, until the stop codon was reached. Such primers were designed based on in silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain -  
25           cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The PCR product derived from exon linking  
30           was cloned into the pCR2.1 vector from Invitrogen. The resulting bacterial clone has an insert covering the entire open reading frame cloned into the pCR2.1 vector. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least  
35           95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported herein.

40           **6. Physical Clone:** Exons were predicted by homology and the intron/exon boundaries were determined using standard genetic rules. Exons were further selected and refined by means of similarity determination using multiple BLAST (for example, tBlastN, BlastX, and BlastN) searches, and, in some instances, GeneScan and Grail. Expressed sequences from both

public and proprietary databases were also added when available to further define and complete the gene sequence. The DNA sequence was then manually corrected for apparent inconsistencies thereby obtaining the sequences encoding the full-length protein.

5 The PCR product derived by exon linking, covering the entire open reading frame, was cloned into the pCR2.1 vector from Invitrogen to provide clones used for expression and screening purposes.

### **Example C: Quantitative expression analysis of clones in various cells and tissues**

10 The quantitative expression of various NOV genes was assessed using microtiter plates containing RNA samples from a variety of normal and pathology-derived cells, cell lines and tissues using real time quantitative PCR (RTQ-PCR) performed on an Applied Biosystems (Foster City, CA) ABI PRISM® 7700 or an ABI PRISM® 7900 HT Sequence Detection System.

15 RNA integrity of all samples was determined by visual assessment of agarose gel electropherograms using 28S and 18S ribosomal RNA staining intensity ratio as a guide (2:1 to 2.5:1 28s:18s) and the absence of low molecular weight RNAs (degradation products). Control samples to detect genomic DNA contamination included RTQ-PCR reactions run in the absence of reverse transcriptase using probe and primer sets designed to amplify across the span of a single exon.

20 RNA samples were normalized in reference to nucleic acids encoding constitutively expressed genes (i.e.,  $\beta$ -actin and GAPDH). Alternatively, non-normalized RNA samples were converted to single strand cDNA (sscDNA) using Superscript II (Invitrogen Corporation, Carlsbad, CA, Catalog No. 18064-147) and random hexamers according to the manufacturer's instructions. Reactions containing up to 10  $\mu$ g of total RNA in a volume of 20  $\mu$ l or were scaled up to contain 50  
25  $\mu$ g of total RNA in a volume of 100  $\mu$ l and were incubated for 60 minutes at 42°C. sscDNA samples were then normalized in reference to nucleic acids as described above.

Probes and primers were designed according to Applied Biosystems *Primer Express* Software package (version I for Apple Computer's Macintosh Power PC) or a similar algorithm using the target sequence as input. Default reaction condition settings and the following  
30 parameters were set before selecting primers: 250 nM primer concentration; 58°-60° C primer melting temperature ( $T_m$ ) range; 59° C primer optimal  $T_m$ ; 2° C maximum primer difference (if probe does not have 5' G, probe  $T_m$  must be 10° C greater than primer  $T_m$ ; and 75 bp to 100 bp amplicon size. The selected probes and primers were synthesized by Synthegen (Houston, TX). Probes were double purified by HPLC to remove uncoupled dye and evaluated by mass  
35 spectroscopy to verify coupling of reporter and quencher dyes to the 5' and 3' ends of the probe, respectively. Their final concentrations were: 900 nM forward and reverse primers, and 200nM probe.

Normalized RNA was spotted in individual wells of a 96 or 384-well PCR plate (Applied Biosystems, Foster City, CA). PCR cocktails included a single gene-specific probe and primers set

or two multiplexed probe and primers sets. PCR reactions were done using TaqMan® One-Step RT-PCR Master Mix (Applied Biosystems, Catalog No. 4313803) following manufacturer's instructions. Reverse transcription was performed at 48° C for 30 minutes followed by amplification/PCR cycles: 95° C 10 min, then 40 cycles at 95° C for 15 seconds, followed by 60° C for 1 minute. Results were recorded as CT values (cycle at which a given sample crosses a threshold level of fluorescence) and plotted using a log scale, with the difference in RNA concentration between a given sample and the sample with the lowest CT value being represented as 2 to the power of delta CT. The percent relative expression was the reciprocal of the RNA difference multiplied by 100. CT values below 28 indicate high expression, between 28 and 32 indicate moderate expression, between 32 and 35 indicate low expression and above 35 reflect levels of expression that were too low to be measured reliably.

Normalized sscDNA was analyzed by RTQ-PCR using 1X TaqMan® Universal Master mix (Applied Biosystems; catalog No. 4324020), following the manufacturer's instructions. PCR amplification and analysis were done as described above.

#### **Panels 1, 1.1, 1.2, and 1.3D**

Panels 1, 1.1, 1.2 and 1.3D included 2 control wells (genomic DNA control and chemistry control) and 94 wells of cDNA samples from cultured cell lines and primary normal tissues. Cell lines were derived from carcinomas (ca) including: lung, small cell (s cell var), non small cell (non-s or non-sm); breast; melanoma; colon; prostate; glioma (glio), astrocytoma (astro) and neuroblastoma (neuro); squamous cell (squam); ovarian; liver; renal; gastric and pancreatic from the American Type Culture Collection (ATCC, Bethesda, MD). Normal tissues were obtained from individual adults or fetuses and included: adult and fetal skeletal muscle, adult and fetal heart, adult and fetal kidney, adult and fetal liver, adult and fetal lung, brain, spleen, bone marrow, lymph node, pancreas, salivary gland, pituitary gland, adrenal gland, spinal cord, thymus, stomach, small intestine, colon, bladder, trachea, breast, ovary, uterus, placenta, prostate, testis and adipose. The following abbreviations are used in reporting the results: metastasis (met); pleural effusion (pl. eff or pl effusion) and \* indicates established from metastasis.

#### **General\_screening\_panel\_v1.4, v1.5, v1.6 and v1.7**

Panels 1.4, 1.5, 1.6 and 1.7 were as described for Panels 1, 1.1, 1.2 and 1.3D, above except that normal tissue samples were pooled from 2 to 5 different adults or fetuses.

#### **Panels 2D, 2.2, 2.3 and 2.4**

Panels 2D, 2.2, 2.3 and 2.4 included 2 control wells and 94 wells containing RNA or cDNA from human surgical specimens procured through the National Cancer Institute's Cooperative Human Tissue Network (CHTN) or the National Disease Research Initiative (NDRI), Ardaís (Lexington, MA) or Clinomics BioSciences (Frederick, MD). Tissues included human malignancies and in some cases matched adjacent normal tissue (NAT). Information regarding histopathological assessment of tumor differentiation grade as well as the clinical stage of the patient from which samples were obtained was generally available. Normal tissue RNA and cDNA samples were

purchased from various commercial sources such as Clontech (Palo Alto, CA), Research Genetics and Invitrogen (Carlsbad, CA).

#### **HASS Panel v 1.0**

5 The HASS Panel v1.0 included 93 cDNA samples and two controls including: 81 samples of cultured human cancer cell lines subjected to serum starvation, acidosis and anoxia according to established procedures for various lengths of time; 3 human primary cells; 9 malignant brain cancers (4 medulloblastomas and 5 glioblastomas); and 2 controls. Cancer cell lines (ATCC) were cultured using recommended conditions and included: breast, prostate, bladder, pancreatic and CNS. Primary human cells were obtained from Clonetics (Walkersville, MD). Malignant brain  
10 samples were gifts from the Henry Ford Cancer Center.

#### **ARDAIS Panel v1.0 and v1.1**

The ARDAIS Panel v1.0 and v1.1 included 2 controls and 22 test samples including: human lung adenocarcinomas, lung squamous cell carcinomas, and in some cases matched adjacent normal tissues (NAT) obtained from Ardais (Lexington, MA). Unmatched malignant and  
15 non-malignant RNA samples from lungs with gross histopathological assessment of tumor differentiation grade and stage and clinical state of the patient were obtained from Ardais.

#### **ARDAIS Prostate v1.0**

ARDAIS Prostate v1.0 panel included 2 controls and 68 test samples of human prostate malignancies and in some cases matched adjacent normal tissues (NAT) obtained from Ardais  
20 (Lexington, MA). RNA from unmatched malignant and non-malignant prostate samples with gross histopathological assessment of tumor differentiation grade and stage and clinical state of the patient were also obtained from Ardais.

#### **ARDAIS Kidney v1.0**

ARDAIS Kidney v1.0 panel included 2 control wells and 44 test samples of human renal  
25 cell carcinoma and in some cases matched adjacent normal tissue (NAT) obtained from Ardais (Lexington, MA). RNA from unmatched renal cell carcinoma and normal tissue with gross histopathological assessment of tumor differentiation grade and stage and clinical state of the patient were also obtained from Ardais.

#### **ARDAIS Breast v1.0**

30 ARDAIS Breast v1.0 panel included 2 control wells and 71 test samples of human breast malignancies and in some cases matched adjacent normal tissue (NAT) obtained from Ardais (Lexington, MA). RNA from unmatched malignant and non-malignant breast samples with gross histopathological assessment of tumor differentiation grade and stage and clinical state of the patient were also obtained from Ardais.

#### **35 Panel 3D, 3.1 and 3.2**

Panels 3D, 3.1, and 3.2 included two controls, 92 cDNA samples of cultured human cancer cell lines and 2 samples of human primary cerebellum. Cell lines (ATCC, National Cancer Institute (NCI), German tumor cell bank) were cultured as recommended and were derived from:

squamous cell carcinoma of the tongue, melanoma, sarcoma, leukemia, lymphoma, and epidermoid, bladder, pancreas, kidney, breast, prostate, ovary, uterus, cervix, stomach, colon, lung and CNS carcinomas.

#### **Panels 4D, 4R, and 4.1D**

5           Panels 4D, 4R, and 4.1D included 2 control wells and 94 test samples of RNA (Panel 4R) or cDNA (Panels 4D and 4.1D) from human cell lines or tissues related to inflammatory conditions. Controls included total RNA from normal tissues such as colon, lung (Stratagene, La Jolla, CA), thymus and kidney (Clontech, Palo Alto, CA). Total RNA from cirrhotic and lupus kidney was obtained from BioChain Institute, Inc., (Hayward, CA). Crohn's intestinal and ulcerative colitis  
10   samples were obtained from the National Disease Research Interchange (NDRI, Philadelphia, PA). Cells purchased from Clonetics (Walkersville, MD) included: astrocytes, lung fibroblasts, dermal fibroblasts, coronary artery smooth muscle cells, small airway epithelium, bronchial epithelium, microvascular dermal endothelial cells, microvascular lung endothelial cells, human pulmonary aortic endothelial cells, and human umbilical vein endothelial. These primary cell types  
15   were activated by incubating with various cytokines (IL-1 beta ~1-5 ng/ml, TNF alpha ~5-10 ng/ml, IFN gamma ~20-50 ng/ml, IL-4 ~5-10 ng/ml, IL-9 ~5-10 ng/ml, IL-13 5-10 ng/ml) or combinations of cytokines as indicated. Starved endothelial cells were cultured in the basal media (Clonetics, Walkersville, MD) with 0.1% serum.

          Mononuclear cells were prepared from blood donations using Ficoll. LAK cells were  
20   cultured in culture media [DMEM, 5% FCS (Hyclone, Logan, UT), 100 mM non essential amino acids (Gibco/Life Technologies, Rockville, MD), 1 mM sodium pyruvate (Gibco), mercaptoethanol  $5.5 \times 10^{-5}$  M (Gibco), and 10 mM Hepes (Gibco)] and interleukin 2 for 4-6 days. Cells were activated with 10-20 ng/ml PMA and 1-2 µg/ml ionomycin, 5-10 ng/ml IL-12, 20-50 ng/ml IFN gamma or 5-10 ng/ml IL-18 for 6 hours. In some cases, mononuclear cells were cultured for 4-5  
25   days in culture media with ~5 mg/ml PHA (phytohemagglutinin) or PWM (pokeweed mitogen; Sigma-Aldrich Corp., St. Louis, MO). Samples were taken at 24, 48 and 72 hours for RNA preparation. MLR (mixed lymphocyte reaction) samples were obtained by taking blood from two donors, isolating the mononuclear cells using Ficoll and mixing them 1:1 at a final concentration of  $\sim 2 \times 10^6$  cells/ml in culture media. The MLR samples were taken at various time points from 1-7  
30   days for RNA preparation.

          Monocytes were isolated from mononuclear cells using CD14 Miltenyi Beads, +ve VS selection columns and a Vario Magnet (Miltenyi Biotec, Auburn, CA) according to the manufacturer's instructions. Monocytes were differentiated into dendritic cells by culturing in culture media with 50 ng/ml GM-CSF and 5 ng/ml IL-4 for 5-7 days. Macrophages were prepared  
35   by culturing monocytes for 5-7 days in culture media with ~50 ng/ml 10% type AB Human Serum (Life technologies, Rockville, MD) or MCSF (Macrophage colony stimulating factor; R&D, Minneapolis, MN). Monocytes, macrophages and dendritic cells were stimulated for 6 or 12-14 hours with 100 ng/ml lipopolysaccharide (LPS). Dendritic cells were also stimulated with 10 µg/ml anti-CD40 monoclonal antibody (Pharmingen, San Diego, CA) for 6 or 12-14 hours.

CD4<sup>+</sup> lymphocytes, CD8<sup>+</sup> lymphocytes and NK cells were also isolated from mononuclear cells using CD4, CD8 and CD56 Miltenyi beads, positive VS selection columns and a Vario Magnet (Miltenyi Biotec, Auburn, CA) according to the manufacturer's instructions. CD45<sup>+</sup>RA and CD45<sup>+</sup>RO CD4<sup>+</sup> lymphocytes were isolated by depleting mononuclear cells of CD8<sup>+</sup>, CD56<sup>+</sup>,  
5 CD14<sup>+</sup> and CD19<sup>+</sup> cells using CD8, CD56, CD14 and CD19 Miltenyi beads and positive selection. CD45RO Miltenyi beads were then used to separate the CD45<sup>+</sup>RO CD4<sup>+</sup> lymphocytes from CD45<sup>+</sup>RA CD4<sup>+</sup> lymphocytes. CD45<sup>+</sup>RA CD4<sup>+</sup>, CD45<sup>+</sup>RO CD4<sup>+</sup> and CD8<sup>+</sup> lymphocytes were cultured in culture media at 10<sup>6</sup> cells/ml in culture plates precoated overnight with 0.5 mg/ml anti-CD28 (Pharmingen, San Diego, CA) and 3 µg/ml anti-CD3 (OKT3, ATCC) in PBS. After 6 and  
10 24 hours, the cells were harvested for RNA preparation. To prepare chronically activated CD8<sup>+</sup> lymphocytes, isolated CD8<sup>+</sup> lymphocytes were activated for 4 days on anti-CD28, anti-CD3 coated plates and then harvested and expanded in culture media with IL-2 (1 ng/ml). These CD8<sup>+</sup> cells were activated again with plate bound anti-CD3 and anti-CD28 for 4 days and expanded as described above. RNA was isolated 6 and 24 hours after the second activation and after 4 days of  
15 the second expansion culture. Isolated NK cells were cultured in culture media with 1 ng/ml IL-2 for 4-6 days before RNA was prepared.

B cells were prepared from minced and sieved tonsil tissue (NDRI). Tonsil cells were pelleted and resuspended at 10<sup>6</sup> cells/ml in culture media. Cells were activated using 5 µg/ml PWM (Sigma-Aldrich Corp., St. Louis, MO) or ~10 µg/ml anti-CD40 (Pharmingen, San Diego, CA) and  
20 5-10 ng/ml IL-4. Cells were harvested for RNA preparation after 24, 48 and 72 hours.

To prepare primary and secondary Th1/Th2 and Tr1 cells, umbilical cord blood CD4<sup>+</sup> lymphocytes (Poietic Systems, German Town, MD) were cultured at 10<sup>5</sup>-10<sup>6</sup> cells/ml in culture media with IL-2 (4 ng/ml) in 6-well Falcon plates (precoated overnight with 10 µg/ml anti-CD28 (Pharmingen) and 2 µg/ml anti-CD3 (OKT3; ATCC) then washed twice with PBS).

25 To stimulate Th1 phenotype differentiation, IL-12 (5 ng/ml) and anti-IL4 (1 µg/ml) were used; for Th2 phenotype differentiation, IL-4 (5 ng/ml) and anti-IFN gamma (1 µg/ml) were used; and for Tr1 phenotype differentiation, IL-10 (5 ng/ml) was used. After 4-5 days, the activated Th1, Th2 and Tr1 lymphocytes were washed once with DMEM and expanded for 4-7 days in culture media with IL-2 (1 ng/ml). Activated Th1, Th2 and Tr1 lymphocytes were re-stimulated for 5 days  
30 with anti-CD28/CD3 and cytokines as described above with the addition of anti-CD95L (1 µg/ml) to prevent apoptosis. After 4-5 days, the Th1, Th2 and Tr1 lymphocytes were washed and expanded in culture media with IL-2 for 4-7 days. Activated Th1 and Th2 lymphocytes were maintained for a maximum of three cycles. RNA was prepared from primary and secondary Th1, Th2 and Tr1 after 6 and 24 hours following the second and third activations with plate-bound anti-CD3 and  
35 anti-CD28 mAbs and 4 days into the second and third expansion cultures.

Leukocyte cell lines Ramos, EOL-1, KU-812 were obtained from the ATCC. EOL-1 cells were further differentiated by culturing in culture media at 5 x10<sup>5</sup> cells/ml with 0.1 mM dbcAMP for 8 days, changing the media every 3 days and adjusting the cell concentration to 5 x10<sup>5</sup> cells/ml. RNA was prepared from resting cells or cells activated with PMA (10 ng/ml) and ionomycin (1

µg/ml) for 6 and 14 hours. RNA was prepared from resting CCD 1106 keratinocyte cell line (ATCC) or from cells activated with ~5 ng/ml TNF alpha and 1 ng/ml IL-1 beta. RNA was prepared from resting NCI-H292, airway epithelial tumor cell line (ATCC) or from cells activated for 6 and 14 hours in culture media with 5 ng/ml IL-4, 5 ng/ml IL-9, 5 ng/ml IL-13, and 25 ng/ml IFN gamma.

5 RNA was prepared by lysing approximately  $10^7$  cells/ml using Trizol (Gibco BRL) then adding 1/10 volume of bromochloropropane (Molecular Research Corporation, Cincinnati, OH), vortexing, incubating for 10 minutes at room temperature and then spinning at 14,000 rpm in a Sorvall SS34 rotor. The aqueous phase was placed in a 15 ml Falcon Tube and an equal volume of isopropanol was added and left at -20° C overnight. The precipitated RNA was spun down at  
10 9,000 rpm for 15 min and washed in 70% ethanol. The pellet was redissolved in 300 µl of RNase-free water with 35 ml buffer (Promega, Madison, WI) 5 µl DTT, 7 µl RNasin and 8 µl DNase and incubated at 37° C for 30 minutes to remove contaminating genomic DNA, extracted once with phenol chloroform and re-precipitated with 1/10 volume of 3 M sodium acetate and 2 volumes of 100% ethanol. The RNA was spun down, placed in RNase free water and stored at -  
15 80° C.

#### **AI\_comprehensive panel\_v1.0**

Autoimmunity (AI) comprehensive panel v1.0 included two controls and 89 cDNA test samples isolated from male (M) and female (F) surgical and postmortem human tissues that were obtained from the Backus Hospital and Clinomics (Frederick, MD). Tissue samples included :  
20 normal, adjacent (Adj); matched normal adjacent (match control); joint tissues (synovial (Syn) fluid, synovium, bone and cartilage, osteoarthritis (OA), rheumatoid arthritis (RA)); psoriatic; ulcerative colitis colon; Crohns disease colon; and emphysematic, asthmatic, allergic and chronic obstructive pulmonary disease (COPD) lung.

#### **Pulmonary and General inflammation (PGI) panel v1.0**

25 Pulmonary and General inflammation (PGI) panel v1.0 included two controls and 39 test samples isolated as surgical or postmortem samples. Tissue samples include: five normal lung samples obtained from Maryland Brain and Tissue Bank, University of Maryland (Baltimore, MD), International Bioresource systems, IBS (Tuscon, AZ), and Asterand (Detroit, MI), five normal adjacent intestine tissues (NAT) from Ardais (Lexington, MA), ulcerative colitis samples (UC) from  
30 Ardais (Lexington, MA); Crohns disease colon from NDRI, National Disease Research Interchange (Philadelphia, PA); emphysematous tissue samples from Ardais (Lexington, MA) and Genomic Collaborative Inc. (Cambridge, MA), asthmatic tissue from Maryland Brain and Tissue Bank, University of Maryland (Baltimore, MD) and Genomic Collaborative Inc (Cambridge, MA) and fibrotic tissue from Ardais (Lexington, MA) and Genomic Collaborative (Cambridge, MA).

#### **35 Cellular OA/RA Panel**

Cellular OA/RA panel includes 2 control wells and 35 test samples comprised of cDNA generated from total RNA isolated from human cell lines or primary cells representative of the human joint and its inflammatory condition. Cell types included normal human osteoblasts (Nhost)

from Clonetics (Cambrex, East Rutherford, NJ), human chondrosarcoma SW1353 cells from ATCC (Manassas, VA)), human fibroblast-like synoviocytes from Cell Applications, Inc. (San Diego, CA) and MH7A cell line (a rheumatoid fibroblast-like synoviocytes transformed with SV40 T antigen) from Riken Cell bank (Tsukuba Science City, Japan). These cell types were activated by incubating with various cytokines (IL-1 beta ~1-10 ng/ml, TNF alpha ~5-50 ng/ml, or prostaglandin E2 for Nhost cells) for 1, 6, 18 or 24 h. All these cells were starved for at least 5 h and cultured in their corresponding basal medium with ~ 0.1 to 1 % FBS.

#### **Minitissue OA/RA Panel**

The OA/RA mini panel includes two control wells and 31 test samples comprised of cDNA generated from total RNA isolated from surgical and postmortem human tissues obtained from the University of Calgary (Alberta, Canada), NDRI (Philadelphia, PA), and Arda's Corporation (Lexington, MA). Joint tissue samples include synovium, bone and cartilage from osteoarthritic and rheumatoid arthritis patients undergoing reconstructive knee surgery, as well as, normal synovium samples (RNA and tissue). Visceral normal tissues were pooled from 2-5 different adults and included adrenal gland, heart, kidney, brain, colon, lung, stomach, small intestine, skeletal muscle, and ovary.

#### **AI.05 chondrosarcoma**

AI.05 chondrosarcoma plates included SW1353 cells (ATCC) subjected to serum starvation and treated for 6 and 18 h with cytokines that are known to induce MMP (1, 3 and 13) synthesis (e.g. IL1beta). These treatments included: IL-1beta (10 ng/ml), IL-1beta + TNF-alpha (50 ng/ml), IL-1beta + Oncostatin (50 ng/ml) and PMA (100 ng/ml). Supernatants were collected and analyzed for MMP 1, 3 and 13 production. RNA was prepared from these samples using standard procedures.

#### **Panels 5D and 5I**

Panel 5D and 5I included two controls and cDNAs isolated from human tissues, human pancreatic islets cells, cell lines, metabolic tissues obtained from patients enrolled in the Gestational Diabetes study (described below), and cells from different stages of adipocyte differentiation, including differentiated (AD), midway differentiated (AM), and undifferentiated (U; human mesenchymal stem cells).

Gestational Diabetes study subjects were young (18 - 40 years), otherwise healthy women with and without gestational diabetes undergoing routine (elective) Caesarean section. Uterine wall smooth muscle (UT), visceral (Vis) adipose, skeletal muscle (SK), placenta (PI) greater omentum adipose (GO Adipose) and subcutaneous (SubQ) adipose samples (less than 1 cc) were collected, rinsed in sterile saline, blotted and flash frozen in liquid nitrogen. Patients included: Patient 2, an overweight diabetic Hispanic not on insulin; Patient 7-9, obese non-diabetic Caucasians with body mass index (BMI) greater than 30; Patient 10, an overweight diabetic Hispanic, on insulin; Patient 11, an overweight nondiabetic African American; and Patient 12, a diabetic Hispanic on insulin.

Differentiated adipocytes were obtained from induced donor progenitor cells (Clonetics, Walkersville, MD). Differentiated human mesenchymal stem cells (HuMSCs) were prepared as described in Mark F. Pittenger, et al., Multilineage Potential of Adult Human Mesenchymal Stem Cells *Science* Apr 2 1999: 143-147. mRNA was isolated and sscDNA was produced from Trizol lysates or frozen pellets. Human cell lines (ATCC, NCI or German tumor cell bank) included: kidney proximal convoluted tubule, uterine smooth muscle cells, small intestine, liver HepG2 cancer cells, heart primary stromal cells and adrenal cortical adenoma cells. Cells were cultured, RNA extracted and sscDNA was produced using standard procedures.

Panel 5I also contains pancreatic islets (Diabetes Research Institute at the University of Miami School of Medicine).

#### **Human Metabolic RTQ-PCR Panel**

Human Metabolic RTQ-PCR Panel included two controls (genomic DNA control and chemistry control) and 211 cDNAs isolated from human tissues and cell lines relevant to metabolic diseases. This panel identifies genes that play a role in the etiology and pathogenesis of obesity and/or diabetes. Metabolic tissues including placenta (Pl), uterine wall smooth muscle (Ut), visceral adipose, skeletal muscle (Sk) and subcutaneous (SubQ) adipose were obtained from the Gestational Diabetes study (described above). Included in the panel are: Patients 7 and 8, obese non-diabetic Caucasians; Patient 12 a diabetic Caucasian with unknown BMI, on insulin (treated); Patient 13, an overweight diabetic Caucasian, not on insulin (untreated); Patient 15, an obese, untreated, diabetic Caucasian; Patient 17 and 25, untreated diabetic Caucasians of normal weight; Patient 18, an obese, untreated, diabetic Hispanic; Patient 19, a non-diabetic Caucasian of normal weight; Patient 20, an overweight, treated diabetic Caucasian; Patient 21 and 23, overweight non-diabetic Caucasians; Patient 22, a treated diabetic Caucasian of normal weight; Patient 23, an overweight non-diabetic Caucasian; and Patients 26 and 27, obese, treated, diabetic Caucasians.

Total RNA was isolated from metabolic tissues including: hypothalamus, liver, pancreas, pancreatic islets, small intestine, psoas muscle, diaphragm muscle, visceral (Vis) adipose, subcutaneous (SubQ) adipose and greater omentum (Go) from 12 Type II diabetic (Diab) patients and 12 non diabetic (Norm) at autopsy. Control diabetic and non-diabetic subjects were matched where possible for: age; sex, male (M); female (F); ethnicity, Caucasian (CC); Hispanic (HI); African American (AA); Asian (AS); and BMI, 20-25 (Low BM), 26-30 (Med BM) or overweight (Overwt), BMI greater than 30 (Hi BMI) (obese).

RNA was extracted and ss cDNA was produced from cell lines (ATCC) by standard methods.

#### **CNS Panels**

CNS Panels CNSD.01, CNS Neurodegeneration V1.0 and CNS Neurodegeneration V2.0 included two controls and 46 to 94 test cDNA samples isolated from postmortem human brain tissue obtained from the Harvard Brain Tissue Resource Center (McLean Hospital). Brains were

removed from calvaria of donors between 4 and 24 hours after death, and frozen at -80° C in liquid nitrogen vapor.

#### **Panel CNSD.01**

Panel CNSD.01 included two specimens each from: Alzheimer's disease, Parkinson's disease, Huntington's disease, Progressive Supranuclear Palsy (PSP), Depression, and normal controls. Collected tissues included: cingulate gyrus (Cing Gyr), temporal pole (Temp Pole), globus pallidus (Glob pallidus), substantia nigra (Sub Nigra), primary motor strip (Brodman Area 4), parietal cortex (Brodman Area 7), prefrontal cortex (Brodman Area 9), and occipital cortex (Brodman area 17). Not all brain regions are represented in all cases.

#### **Panel CNS Neurodegeneration V1.0**

The CNS Neurodegeneration V1.0 panel included: six Alzheimer's disease (AD) brains and eight normals which included no dementia and no Alzheimer's like pathology (control) or no dementia but evidence of severe Alzheimer's like pathology (Control Path), specifically senile plaque load rated as level 3 on a scale of 0-3; 0 no evidence of plaques, 3 severe AD senile plaque load. Tissues collected included: hippocampus, temporal cortex (Brodman Area 21), parietal cortex (Brodman area 7), occipital cortex (Brodman area 17) superior temporal cortex (Sup Temporal Ctx) and inferior temporal cortex (Inf Temporal Ctx).

Gene expression was analyzed after normalization using a scaling factor calculated by subtracting the Well mean (CT average for the specific tissue) from the Grand mean (average CT value for all wells across all runs). The scaled CT value is the result of the raw CT value plus the scaling factor.

#### **Panel CNS Neurodegeneration V2.0**

The CNS Neurodegeneration V2.0 panel included sixteen cases of Alzheimer's disease (AD) and twenty-nine normal controls (no evidence of dementia prior to death) including fourteen controls (Control) with no dementia and no Alzheimer's like pathology and fifteen controls with no dementia but evidence of severe Alzheimer's like pathology (AH3), specifically senile plaque load rated as level 3 on a scale of 0-3; 0 no evidence of plaques, 3 severe AD senile plaque load. Tissues from the temporal cortex (Brodman Area 21) included the inferior and superior temporal cortex that was pooled from a given individual (Inf & Sup Temp Ctx Pool).

#### **A. NOV1, CG101729-02: FGFR4 variant.**

Expression of gene CG101729-02 was assessed using the primer-probe sets Ag4038, Ag4044 and Ag7932, described in Tables AA, AB and AC. Results of the RTQ-PCR runs are shown in Tables AD, AE, AF and AG. CG101729-02 represents a full-length physical clone.

- 5 **AI\_comprehensive\_panel\_v1.0 Summary:** Ag4044/Ag4038 Moderate levels of expression of this gene were detected in all the samples derived from rheumatoid arthritis bone and adjacent bone, cartilage, synovium and synovial fluid samples, while no expression could be seen in normal control samples. Therefore, modulation of this gene, encoded protein and/or use of antibodies or small molecule targeting this gene or gene product is useful in the treatment of
- 10 inflammatory and autoimmune diseases such as rheumatoid arthritis.

**General\_screening\_panel\_v1.7 Summary:** Ag7932 and Ag7932 are specific to the deletion splice variant of FGFR4, CG101729-02. The expression of this soluble FGFR4 variant was elevated in a number of ovarian cancer cell lines. The gene's expression is useful in differentiating ovarian cancer from normal ovarian tissue. Therapeutic modulation of this soluble

form of FGFR4, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product would be useful in the treatment of ovarian cancer.

**PGI1.0 Summary:** Ag4044 Elevated expression levels of this gene were detected in diseased lung tissues with Fibrosis, Asthma, and Emphysema as compared with normal lung tissues. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product would be useful in the treatment of Fibrosis, Asthma, and Emphysema.

**general oncology screening panel\_v\_2.4 Summary:** Ag4044/Ag4038 Elevated expression levels of this gene were detected in colon cancer samples as compared to normal adjacent tissues. The gene's expression is useful in differentiating colon cancer tissue from normal colon tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of colon cancer.

#### B. NOV3, CG185793-02: MMP15.

Expression of gene CG185793-02 was assessed using the primer-probe sets Ag3682 and Ag7951, described in Tables BA and BB. Results of the RTQ-PCR runs are shown in Tables BC and BD.

**Table BA. Probe Name Ag3682**

**General\_screening\_panel\_v1.7 Summary:** Ag7951 Highest gene expression was detected in Thyroid (CT=9.5). Moderate gene expression was seen in spleen, brain, kidney, skeletal muscle, liver, colon, and lung. This ubiquitous pattern of expression indicates that this gene product is involved in homeostatic processes for these and other cell types and tissues. This gene was expressed at much higher level in fetal (CT=32.3) when compared to adult heart (CT=35). This observation indicates that the protein product may enhance heart growth or development in the fetus and thus act in a regenerative capacity in the adult. This gene's expression is useful in distinguishing fetal heart tissue from adult heart tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in treatment of heart related diseases.

**general oncology screening panel\_v\_2.4 Summary:** Ag3682 Highest gene expression was detected in a malignant colon cancer sample (CT=27.96). Expression of this gene was upregulated in all lung cancer and prostate cancer samples when compared to the matched control margins. Moderate expression of this gene was seen in all melanoma samples. Therefore, expression of this gene is useful to differentiate lung, prostate and melanoma cancerous tissues from corresponding normal tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product would be useful in the treatment of melanoma, prostate, and lung cancers.

### C. NOV6 CG54470: FGF19-X.

Expression of gene CG54470 was assessed using the primer-probe sets Ag78b and Ag78, described in Tables CA and CB. Results of the RTQ-PCR runs are shown in Tables CC and CD.

**Panel 1.3D Summary:** Ag78b Moderate gene expression was detected in cancer cell lines derived from lung, while no expression was seen in normal lung tissue. Thus, the gene's expression is useful in differentiating lung cancer from normal lung tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of lung cancer.

**Panel 2D Summary:** Ag78 Gene expression was highest in a sample derived from normal liver tissue adjacent to a colon cancer metastasis. In addition, there was substantial expression in samples derived from normal liver and liver cancers as well as a sample derived from liver tissue adjacent to an ocular melanoma metastasis. Of particular interest is the difference in expression of this gene between liver cancers and their adjacent normal tissues. There was a 20-fold and 2-fold difference in expression between liver cancer samples when compared to

matched margins (6004-T vs 6004-N and 6005-T vs 6005-N, respectively). Gene expression is useful in differentiating liver cancer tissue from normal liver tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of liver cancer.

5 **D. NOV7, CG55051: Alpha-2-macroglobulin like.**

Expression of gene CG55051 was assessed using the primer-probe sets Ag1180 and Ag1312, described in Tables DA and DB. Results of the RTQ-PCR runs are shown in Tables DC, DD, DE and DF.

**AI\_comprehensive panel\_v1.0 Summary:** Ag1180 High gene expression was detected in Crohns tissues from female patients, while no expression was detected in Crohns samples from male patients. The gene's expression is useful in differentiating Crohns disease colon tissue from normal colon tissue in female patients. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of Crohns disease and other inflammatory disorders including psoriasis, allergy, asthma, inflammatory bowel disease, rheumatoid arthritis and osteoarthritis.

**Panel 1.3D Summary:** Ag1180 Moderate levels of gene expression were detected in gastric cancer cell lines (CT=30.4) and lower levels in pancreatic cancer cell lines (CT = 33.5). Gene expression is useful for differentiating gastric and pancreatic cancerous tissue from normal tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of gastric and pancreatic cancers. Low levels of gene expression was detected in brain. Among tissues involved in central nervous system function, this gene is specifically expressed at low to moderate levels in the amygdala, cerebellum, cortex, hippocampus and thalamus, and expressed highly in the spinal cord and cerebral cortex. Alpha-2-macroglobulin has been implicated in Alzheimer's disease, both genetically and biochemically in the clearance of beta amyloid. The high similarity of this gene's protein product to alpha-2-macroglobulin suggests indicates its involvement in Alzheimer's. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of Alzheimer's disease. Agents that increase expression, concentration, or activity of this gene will aid in the clearance of A-beta, which is a hallmark of Alzheimer's disease histopathology.

**Panel 2D Summary:** Ag1180 Highest gene expression was detected in ovarian cancer tissue (CT = 25.67) and it is overexpressed in ovarian cancer samples when compared to the normal margins. There was low but significant expression of this gene in some breast, bladder, and lung cancer samples. Expression of this gene can be used to differentiate ovarian breast, bladder, and lung cancerous tissue from normal specimens. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product would be useful in the treatment of bladder, ovarian, breast, and lung cancer.

**Panel 4D Summary:** Ag1180/Ag1312 Expression of this gene was detected at moderate levels in small airway epithelium (CT = 28) and is slightly upregulated when treated with TNF-alpha + IL-1beta (CT = 26-27). This gene encodes a protein that is a macroglobulin-like molecule belonging to a class of proteinase inhibitor that can behave as a potent modulator of the inflammatory reaction and tissue repair mechanism. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of asthma and emphysema. Expression of this gene was detected in keratinocytes stimulated with the inflammatory cytokines TNF-alpha + IL-1beta (CT =

29). The gene's expression is useful in differentiating keratinocytes stimulated with the inflammatory cytokines TNF-alpha + IL-1beta from unstimulated keratinocytes. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product would be useful in the treatment of skin related disease such as psoriasis, eczema, and contact dermatitis.

#### E. NOV 8, CG55060: SLPI.

Expression of gene CG55060 was assessed using the primer-probe set Ag588, described in Table EA. Results of the RTQ-PCR runs are shown in Tables EB, EC, ED, EE, EF and EG.

**Ardais Kidney 1.0 Summary:** Ag588 High gene expression was detected in kidney cancer samples. The gene's expression is useful in differentiating kidney cancer tissue from normal kidney tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of kidney cancer.

**CNS\_neurodegeneration\_v1.0 Summary:** Ag588 Moderate expression levels of this gene were detected in brain in an independent group of individuals. This gene was slightly upregulated in the temporal cortex of Alzheimer's disease patients. The gene's expression is useful in differentiating temporal cortex tissue of Alzheimer's disease patients from normal temporal cortex tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of Alzheimer's disease.

**General\_screening\_panel\_v1.5 Summary:** Ag588 Highest expression of this gene was seen in the trachea (CT=18). High levels of expression were also seen in ovarian, pancreatic, brain, colon, gastric, and squamous cell carcinoma cell lines. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene

product are useful in the treatment of ovarian, pancreatic, brain, colon, gastric, and squamous cell cancers.

**Panel 2D Summary:** Ag588 Highest expression was detected in an ovarian cancer sample (CTs=22). Gene overexpression was detected ovarian, uterine, thyroid and kidney cancer samples when compared to the expression in normal adjacent tissue. Gene expression is useful for differentiating these cancer samples from other samples on this panel and as a marker of these cancers. This gene encodes secretory leucocyte protease inhibitor (SLPI), a potent inhibitor of granulocyte elastase and cathepsin G, as well as pancreatic enzymes like trypsin, chymotrypsin and pancreatic elastase. SLPI has also been shown to inhibit HIV-1 infections by blocking viral DNA synthesis. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of ovarian, uterine, thyroid, and kidney cancers.

**Panel 4D Summary:** Ag588 Highest gene expression was detected in TNF- $\alpha$ /IL1- $\beta$  treated small airway epithelium. High gene expression were also seen in untreated small airway epithelium, normal lung, and a cluster of treated and untreated samples derived from the NCI-H292 cell line, a human airway epithelial cell line that produces mucins. Mucus overproduction is a feature of bronchial asthma and chronic obstructive pulmonary disease samples. The expression of this gene in the mucoepidermoid cell line NCI-H292 and in small airway epithelium indicates that this gene is involved in the proliferation or activation of airway epithelium. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of symptoms caused by inflammation in lung epithelia in chronic obstructive pulmonary disease, asthma, allergy, and emphysema.

**Panel 5D Summary:** Ag588 Prominent expression of this gene was detected in adipose (CTs=26-27). Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of obesity and diabetes.

#### F. NOV 9, CG56008-01: LIV-1 protein, estrogen regulated.

Expression of gene CG56008-01 was assessed using the primer-probe set Ag2169, described in Table FA. Results of the RTQ-PCR runs are shown in Tables FB, FC, FD, FE, FF, FG and FH.

**Table FA. Probe Name Ag2169**

- 5 **Ardais Panel 1.1 Summary:** Ag2169 Highest gene expression was detected in a lung cancer samples (CT=24.2). Thus, expression of this gene can be used to differentiate between lung cancer tissue and normal lung tissue and as a marker of lung cancer. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of lung cancer

**Panel 1.3D Summary:** Ag2169 The expression of this gene was highest in a sample of breast cancer cell line (MCF-7)(CTs=26). Therapeutic modulation of this gene, through the use of small molecule drugs, antibodies or protein therapeutics is useful in the treatment of breast cancer. Differential expression of this gene can be used to differentiate between breast cancer cells and normal breast cells. This gene was moderately expressed in a variety of metabolic tissues, including pancreas, adrenal, thyroid, pituitary, adult and fetal heart, fetal liver and adipose. As a zinc transporter, this gene is a potential target for the enhancement of insulin secretion and sensitivity in Type 2 diabetes. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of metabolic and endocrine disease, including obesity and Types 1 and 2 diabetes. This gene is differentially expressed in fetal (CTs=31-32) vs adult skeletal muscle (CTs=34-35). The relative overexpression of this gene in fetal skeletal muscle suggests that the protein product may enhance muscular growth or development in the fetus and thus may also act in a regenerative capacity in the adult. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful for restoring muscle mass or function in weak or dystrophic muscle. Among tissues of CNS origin, gene expression was moderate in all regions examined. This gene, a LIV-1 homolog, is involved in zinc homeostasis. Zinc is critical to brain functions as it serves as an endogenous neuromodulator in synaptic neurotransmission. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of learning deficiencies and seizure disorders associated with improper zinc trafficking.

**Panel 2.2 and 2D Summary:** Ag2169 Gene expression was detected in breast cancer, while expression of this gene in other tissues was almost absent with the exception of prostate derived samples. Gene expression is useful distinguish breast cancer samples from the other samples in the panel. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of breast cancer.

**Panel 3D Summary:** Ag2169 The expression of this gene was highest in a sample derived from a lung cancer cell line (DMS 79)(CT=27.8). There were significant levels of expression in other lung cancer cell lines. The expression of this gene can be used to distinguish DMS 79 cells from other samples in the panel. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of lung cancer.

**Panel 4D Summary:** Ag2169 The highest expression of this gene was seen in small airway epithelium stimulated with TNF-alpha and IL-1beta (CTs=27). Moderate expression levels were also seen in pokeweed mitogen-activated peripheral blood mononuclear cells (mainly B cells), ionomycin-activated Ramos B cell, pokeweed mitogen-activated purified peripheral blood B lymphocytes, B lymphocytes activated with CD40L and IL-4, and a number of cytokine-activated and resting cells including NCI-H292 pulmonary mucoepidermoid epithelial cells, lung fibroblasts,

and dermal fibroblasts. Based expression in cytokine-activated B cells and cells in lung and skin, therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of autoimmune and inflammatory diseases in which activated B cells present antigens generating aberrant immune responses, such as, but not limited to Crohn's disease, ulcerative colitis, multiple sclerosis, chronic obstructive pulmonary disease, asthma, emphysema, rheumatoid arthritis, or psoriasis.

**general oncology screening panel\_v\_2.4 Summary:** Ag2169 High gene expression was seen in a prostate cancer, with prominent expression seen in melanoma (CT=28.7) and in colon cancer but not adjacent normal colon tissue. Expression of this gene is useful to differentiate colon cancer from normal colon tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of prostate, colon cancer and melanoma.

#### G. NOV10, CG59356-01: NUCLEAR RECEPTOR SUBFAMILY 4.

Expression of gene CG59356-01 was assessed using the primer-probe set Ag3554, described in TableGA. Results of the RTQ-PCR runs are shown in Tables GB, GC, GD, GE and GF.

**Table GA. Probe Name Ag3554**

**AI\_comprehensive\_panel\_v1.0 Summary:** Ag3554 The highest expression of this gene was detected in a normal lung sample (CT=26). This gene is downregulated in lung samples from patients suffering from COPD, emphysema or asthma. The gene's expression is useful in differentiating COPD, emphysema or asthma lung tissue from normal lung tissue. Therapeutic modulation of this gene or gene product is useful in the treatment of COPD, emphysema or asthma. This gene was upregulated in cartilage, bone, synovium and synovial fluid from rheumatoid arthritic patients and is therefore useful in differentiating these tissues from rheumatoid arthritic verses normal joints. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of rheumatoid arthritis.

**General\_screening\_panel\_v1.4 Summary:** Ag3554 Highest expression of this gene was detected in fetal lung (CT=25.2) and it was overexpressed as compared to adult lung. The gene product enhances lung growth or development in the fetus and thus can also act in a regenerative capacity in the adult. Therapeutic modulation of this gene, expressed protein and/or use of small molecule drugs targeting the gene or gene product are useful in the treatment of lung diseases. High to moderate levels of gene expression were seen in tissues with metabolic/endocrine functions including pancreas, adipose, adrenal gland, thyroid, pituitary gland, skeletal muscle, heart, liver and the gastrointestinal tract. Therapeutic modulation of this gene, expressed protein and/or use of small molecule drugs targeting the gene or gene product are useful in the treatment of endocrine/metabolically related diseases, such as obesity and diabetes. Moderate gene expression was seen in all regions of the central nervous system examined, including amygdala, hippocampus, substantia nigra, thalamus, cerebellum, cerebral cortex, and spinal cord. Therapeutic modulation of this gene, expressed protein and/or use of small molecule drugs targeting the gene or gene product are useful in the treatment of central nervous system disorders such as Alzheimer's disease, Parkinson's disease, epilepsy, multiple sclerosis, schizophrenia and depression.

Significant expression of this gene was also observed in colon cancer tissue and cell lines derived from melanoma, brain, gastric, lung and breast cancers. Gene expression is useful for differentiating these cancerous tissues from their normal counterparts. This gene encodes for nuclear receptor NOR1. In extraskeletal myxoid chondrosarcoma, chromosomal translocation creates a gene fusion between EWS and the orphan nuclear receptor NOR1, EWS/NOR1, which is believed to lead to malignant transformation by functioning as a transcriptional activator or regulator of mRNA splicing (Clark et. al., 1996 Oncogene 12: 229-235, PubMed ID: 8570200;

Ohkura et al., 2002, J Biol Chem 277(1):535-43, PMID: 11673470). Therapeutic modulation of this gene, expressed protein and/or use of small molecule drugs targeting the gene or gene product are useful in the treatment of melanoma, chondrosarcoma, and brain, gastric, lung and breast cancers.

5           **Panel 4.1D Summary:** Ag3554 The highest gene expression was detected in LAK cells treated with PMA and ionomycin (CT=25). This gene was upregulated in stimulated immune cells, including activated primary and secondary Th1 and Th2 cell, activated CD4 lymphocytes, lung fibroblasts treated with interferon gamma, lung fibroblasts treated with TNF alpha and IL-1 beta, and monocytes and macrophages stimulated with LPS. The gene's expression is useful in  
10 differentiating these stimulated immune cell types from resting cells. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of: immunosuppressed individuals, inflammatory disorders and autoimmune diseases, such as asthma, emphysema, allergy, psoriasis, arthritis, ulcerative colitis, rheumatoid disease and inflammatory bowel disease.

15           **Panel 5 Islet Summary:** Ag3554 Highest expression of this gene was detected in adrenocortical adenoma sample (CT=27.9). Thus, this gene may play a role in tumor development. Therapeutic modulation of this gene, expressed protein and/or use of small molecule drugs targeting the gene or gene product are useful in the treatment of adrenocortical adenoma. Moderate levels of gene expression were detected in skeletal muscle and visceral adipose of  
20 obese and diabetic patients. Therapeutic modulation of this gene, expressed protein and/or use of small molecule drugs targeting the gene or gene product are useful in the treatment of obesity and diabetes.

**general oncology screening panel\_v\_2.4 Summary:** Ag3554 The highest expression of this gene was detected in metastatic melanoma sample (CT=26) and this gene was  
25 overexpressed in colon, kidney, prostate and lung cancers when compared to normal adjacent tissues. Gene expression is useful in differentiating colon, kidney, prostate, lung cancer and melanoma tissues from their normal counterparts. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of cancers of the colon, kidney, prostate, skin and lung.

30           **H. NOV11, CG59889-01: KIAA1199, and CG59889-04: KIAA1199 extension.**

Expression of genes CG59889-01 and CG59889-04 was assessed using the primer-probe set Ag3626, described in Table HA. Results of the RTQ-PCR runs are shown in Tables HB, HC, HD and HE.

**AI\_comprehensive panel\_v1.0 Summary:** Ag3626 Transcript expression was higher in some joint tissues isolated from osteoarthritic (OA) patients as compared to normal joint tissues, with highest expression in an OA bone sample (CT=28.5). The gene's expression is useful in differentiating OA joint tissue from normal joint tissue. The transscript or the protein it encodes can be used as a marker for osteoarthritic tissues. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of arthritis:

**Ardais Colon1.0 Summary:** Ag3626 This gene was highly expressed in a colon cancer as compared to their normal adjacent tissue (NAT) counterparts. The gene's expression is useful in differentiating colon cancer tissue from normal colon tissue. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of colon cancer.

**Panel 4.1D Summary:** Ag3626 Highest gene expression was seen in TNF-alpha and IL-1 beta treated astrocytes (CT=26). Therapeutic modulation of this gene and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of inflammatory CNS diseases such as multiple sclerosis. This gene was expressed in certain samples from lung and dermal fibroblasts. Therapeutic modulation of this gene and/or use of

antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of lung inflammatory diseases such as asthma, and chronic obstructive pulmonary diseases, inflammatory skin diseases such as psoriasis, atopic dermatitis, ulcerative dermatitis, ulcerative colitis.

- 5 **general oncology screening panel\_v\_2.4 Summary:** Ag3626 This gene was overexpressed in 4 out of 4 colon cancer and 3 out of 3 lung cancer samples as compared to Normal Adjacent Tissues (NATs). This gene was also expressed in melanoma, prostate adenocarcinoma and kidney cancer samples. The Gene expression is useful in differentiating skin, colon, lung, prostate and kidney cancerous tissues from normal counterparts. Therapeutic
- 10 modulation of this gene and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of cancers of the colon, lung, skin, prostate and kidney.

#### I. NOV12, CG88912-02: BETA-NEOENDORPHIN-DYNORPHIN PRECURSOR.

Expression of gene CG88912-02 was assessed using the primer-probe set Ag7210, described in Table IA. Results of the RTQ-PCR runs are shown in Table IB.

15 **Table IA. Probe Name Ag7210**

- General\_screening\_panel\_v1.7 Summary:** Ag7210 The highest gene expression was detected in ovarian cancer cell line IGROV-1 (CT=23). Gene expression was detected in testis and brain. The gene's expression is useful in differentiating brain and testicular tissues from the other tissues represented on this panel. Therapeutic modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product are useful in the treatment of disorders of the central nervous system including Alzheimer's disease, Parkinson's disease, trauma, stroke, epilepsy, pain, multiple sclerosis, schizophrenia, bipolar disorder, depression, autism, drug and alcohol addiction.

10

#### Example D: Gene Expression analysis using CuraChip in human tissues

- Background:** CuraGen has developed a gene microarray (CuraChip 1.2) for target identification. It provides a high-throughput means of global mRNA expression analyses of CuraGen's collection of cDNA sequences representing the Pharmaceutically Tractable Genome (PTG). This sequence set includes genes which can be developed into protein therapeutics, or used to develop antibody or small molecule therapeutics. CuraChip 1.2 contains ~11,000 oligos

representing approximately 8,500 gene loci, including (but not restricted to) kinases, ion channels, G-protein coupled receptors (GPCRs), nuclear hormone receptors, proteases, transporters, metabolic enzymes, hormones, growth factors, chemokines, cytokines, complement and coagulation factors, and cell surface receptors.

5           The CuraChip cDNAs were represented as 30-mer oligodeoxyribonucleotides (oligos) on a glass microchip. Hybridization methods using the longer CuraChip oligos are more specific compared to methods using 25-mer oligos. CuraChip oligos were synthesized with a linker, purified to remove truncated oligos (which can influence hybridization strength and specificity), and spotted on a glass slide. Oligo-dT primers were used to generate cRNA probes for hybridization  
10       from samples of interest. A biotin-avidin conjugation system was used to detect hybridized probes with a fluorophore-labeled secondary antibody. Gene expression was analyzed using clustering and correlation bioinformatics tools such as Spotfire® (Spotfire, Inc., 212 Elm Street, Somerville, MA 02144) and statistical tools such as multivariate analysis (MVA).

          A number of control spots are present on CuraChip 1.2 for efficiency calculations and to  
15       provide alternative normalization methods. For example, CuraChip 1.2 contains a number of empty or negative control spots, as well as positive control spots containing a dilution series of oligos that detect the highly-expressed genes Ubiquitin and glyceraldehyde-3-phosphate dehydrogenase (GAPD). An analysis of spot signal level was performed using raw data from 67 hybridizations using all oligos. The maximum signal intensity for each oligo across all 67 hybridizations was  
20       determined, and the fold-over-background for this maximum signal was calculated (i.e. if the background reading is 20 and the raw spot intensity is 100, then the fold-over-background for that spot is 5x). The negative control or empty spots do occasionally “fire” or give a signal over the background level; however, they do not fire very strongly, with 77.1% of empty spots firing <3x over background and 91.7% <5x. The positive control spots (Ubiquitin and GAPD) always fired at  
25       >100x background. The experimental oligos (CuraOligos) fired over the entire range of intensities, with some at low fold-over-background intensities. Since the negative control spots do fire occasionally at low levels, we have set a suggested threshold for data analysis at >5x background.

          Approximately 561 samples of RNA from tissues obtained from surgically dissected  
30       diseased- and non-diseased tissues, and treated and untreated cell lines, were used to generate labelled nucleic acid which was hybridized to PTG Chip 1.2. Oligonucleotides corresponding to specific genes under investigation were used to determine gene expression profile.

**I. Expression analysis of NOV2 CG124800-02:** Oligonucleotide (optg2\_0013773,  
35       TAAAGGTCTCCACAGAGTTTATGCCATATT) (SEQ ID NO: 185) corresponding to CG124800-02 was used to determine specific gene expression on PTG Chip 1.2. Elevated levels of gene expression were detected in Alzheimer's disease and colon cancer samples as compared to the normal samples (Table DI). The gene's expression is useful for differentiating Alzheimer's disease brain tissue and colon cancer tissue from normal brain and normal colon, respectively. Therapeutic

modulation of this gene, expressed protein and/or use of antibodies or small molecule drugs targeting the gene or gene product would be useful in the treatment of Alzheimer's disease and colon cancer.

**Table DI: CG124800-02**

**OTHER EMBODIMENTS**

15 Although particular embodiments are disclosed herein in detail, this is done by way of example for purposes of illustration only, and is not intended to be limiting with respect to the scope of the appended claims, which follow. In particular, it is contemplated by the inventors that various substitutions, alterations, and modifications will be made to the invention without departing from the spirit and scope of the invention as defined by the claims. The choice of nucleic acid  
 20 starting material, clone of interest, or library type is believed to be a matter of routine for a person of ordinary skill in the art with knowledge of the embodiments described herein. Other aspects, advantages, and modifications considered to be within the scope of the following claims. The claims presented are representative of the inventions disclosed herein. Other, unclaimed inventions are also contemplated. Applicants reserve the right to pursue such inventions in later  
 25 claims.
